Nature

A WEEKLY

JOURNAL OF SCIENCE

VOLUME CXXXI

JANUARY, 1933, to JUNE, 1933

> " To the solid ground
> Of Nature trusts the mind that builds for aye."—Wordsworth.

310566
IARI

London
MACMILLAN AND CO., Limited
NEW YORK: THE MACMILLAN COMPANY

INDEX

NAME INDEX

Abdouloff (I.), [D. Ivanoff and], Velocity of Disengagement of Hydrocarbons produced by the action of Indene on Fatty Organomagnesium Derivatives, 483

Abe (N.), Age and Growth of Limpets, 30

Abel (E.), and H. Schmid, Flow Kinetics: Model of Photolysis, 251

Abruzzi (Duke of the), [death], 427, [obituary article], 717

Achalme (P.), Chemical Nature of the Neutron, 559

Achard (C.), and A. Boutaric, Suspensions starting with Proteins separated from Serum, 178

Ackermann (A. S. E.), Illuminated Fountains, 396

Ackermann (Dr. W.), Detection of Traces of Carbon Monoxide in Air, 441

Acworth (Capt. B.), Economic Significance of Coal, 478

Adams (L. E.), Moles Storing Worms, 466

Addington (J. N.), Gaseous Tubes for Lighting, 235

Adelsberger [Scheibe and], Oscillating Quartz Crystal as an Accurate Clock, 281

Agello (Warrant Officer F.), New Air Speed Record, 580

Agostinelli (C.), Concurrent Directions in a Variety V_n, 851

Aitken (Dr. A. C.), awarded the Makdougall-Brisbane prize of the Royal Society of Edinburgh, 359

Aiyar (P. R. Chidambara), Earth's Influence on Sunspots, 245

Alcock (Lieut.-Col. A. W.), [death], 462; [obituary article], 273

Alessandri (C.), Apparent Velocity of the Surface Propagation of Earthquakes in relation to the Hypocentral Depth, 923

Alexander (Dr. F.), The Medical Value of Psychoanalysis (*Review*), 532

Alexander (Prof. T.), [death], 266

Alfvén (H.), Origin of Cosmic Radiation, 619

Algar (J.), Isabella M. McCarthy and Eveline M. Dick, Synthesis of Diflavones, 666

Allan (D.), Candles and Candlemaking, 269

Allcock (H. J.), and J. R. Jones, The Nonogram: the Theory and Practical Construction of Computation Charts (*Review*), 785

Allen (Dr. E. J.), Prof. Johannes Schmidt, 424

Allen (W. E. D.), A History of the Georgian People: from the Beginning down to the Russian Conquest in the Nineteenth Century (*Review*), 308

Allibone (T. E.), F. S. Edwards, and D. B. McKenzie, A New Impulse Generator for Three Million Volts, 129

Allix (A.), Progressive Darkening of the Lyons Atmosphere, 179

Allmand (Prof. A. J.), Photochemical Reaction of Hydrogen and Chlorine, 656; Simple Molecules and Elementary Processes, 173

Aloisi (P.), An Andalusite Twin, 851

Alpatov (Dr.), Egg Production in Vestigial- and Long-Winged Flies, 176

Alter [Baxter and], Lead from Cyrtolite, 881

Amati (A.), [G. Mezzadroli and], Action of certain Alkaloids on the Development of *Aspergillus niger*, 339

Ambler (H. R.), and T. C. Sutton, Detection of traces of Carbon Monoxide in Air, 756

Amiel (J.), Slow Combustion of Benzene, 774

Anderson (J.), appointed professor of surgery in St. Andrews University, 848

Anderson (R. M.), Methods of Collecting and Preserving Vertebrate Animals, 906

Anderson, Wilson Photographs of Cosmic Ray Phenomena, 590

Andrewes (late Sir Frederick W.), and Mrs. Ethel M. Christie, The Hæmolytic Streptococci: their Grouping by Agglutination, 593

Anniss (L. G.), Upper Devonian Rocks of the Chudleigh Area, South Devon, 482

Anstey (Dr. Vera), appointed Cassel lecturer in commerce at the London School of Economics, 480

Antoniadi (Dr. E. M.), The Minor Details of the Planet Mars, 802

Antoniani (C.), the Phytosterol Group (2), 483; and F. Zanelli, Cholesterol of the Human Brain, 71

Appleton (Prof. E. V.), Fine Structure of the Ionosphere, 872; Thermionic Vacuum Tubes and their Applications (*Review*), 9; and R. Naismith, Kennelly-Heaviside Layer, 808; Weekly Measurements of Upper Atmospheric Ionisation, 522

Appleyard (R.), Charles Parsons: his Life and Work (*Review*), 891

Armstrong (Dr. E. F.), Enzymes: a Discovery and its Consequences, 535; Alcohol through the Ages, 810; Chemistry and our Idiosyncrasies (*Review*), 314; and others, Utilisation of Coal, 479

Armstrong (Prof. H. E.), Agriculture and Milk Supply, 605; An Indian Sage (*Review*), 672; Caution in Christening, 330; Chemistry and the Art of Living (Sir Jesse Boot Foundation lecture), 795; elected president of the Lancaster Frankland Chemical Society, 197; Huxley and Scientific Education, 684; In Chase of Truth of Alcohol, 53; the Work of Sir Edward Frankland, 196

Arakatsu (B.), Anomalous Absorption of γ-Rays, 696

Arend [Delporte and], A Remarkable Short-Lived Nova, 553

Arnaud (F. W. F.), elected president of the Society of Public Analysts, 359

Arrow (G. J.), and others. Edited by W. P. Pycraft, The Standard Natural History: from Amœba to Man (*Review*), 152

Ashworth (Prof. J. H.), Lieut.-Col. J. Stephenson, 193

Aston (Dr. F. W.), Physical Atomic Weights, 172

Atkins (Dr. W. R. G.), [Dr. H. H. Poole and], Photocells of the Dry Rectifier Type for the Measurement of Daylight, 850; Reversal of Current in Rectifier Photo-Cells, 547; Reversal of the Current from a Cuprous Oxide Photo-Cell in Red Light, 133

Atkinson (Ll. B.), elected an honorary member of the Institution of Electrical Engineers, 128

Atmanathan (S.), Katabatic Winds, 696

Atta (Van), [Van de Graaf, Compton and], Electrostatic Production of High Voltages, 475

Audubert (R.), Differentiation of the Electronic Effects and the Photoelectric Effects in Photovoltaic Elements, 482

Auger (P.), and G. M. Herzen, Emission of Neutrons by Aluminium under the Action of the α-Particles, 523
Aung (Maung Htin), Burmese Spirit-World, 767
Austen (Major E. E.), and A. W. McKenny Hughes, Clothes Moths and House Moths, 55
Awbery (J. H.), and Dr. E. Griffiths, Heats of Combustion of Carbon Monoxide in Oxygen and of Nitrous Oxide in Carbon Monoxide at Constant Pressure, 110
Aynsley (E. E.), Dr. T. G. Pearson and Dr. P. L. Robinson, New Experimental Evidence in the Sulphur-Hydrogen Reaction, 471

Babington (Dr. William), Centenary of the Death of, the Work of, 613
Bacharach (A. L.), Research on Vitamins (*Review*), 857; Vitamin C and Ascorbic Acid, 364
Backlund (Dr. N. O.), Dewaxing and Acid Refining Mineral Oils, 31
Badcock (W. C.), and Dr. E. J. Holmyard, Electricity and Magnetism for Beginners (*Review*), 347
Badouin (M.), An Intentional Fabrication of an Engraving of a Horse's Hoof on Granite, by means of a Stone Tool, 375
Bailey (Alice A.), Ultra-Violet Light and Fungi, 404; [G. B. Ramsey and], Tomato Late-Blight Rot, 440
Bailey (C. R.), and A. B. D. Cassie, Form and Vibrational Frequencies of the Nitrogen Dioxide Molecule, 910; Infra-Red Absorption Spectrum of Nitrogen Dioxide, 239; Infra-Red Region of the Spectrum (8), 286
Bailey (Prof. E. B.), Help from America in Reading Scottish Tectonics, 522; and Dr. J. Weir, Submarine Faulting in Kimmeridgian Times, 244
Bailey (Dr. K. C.), [T. N. Richardson and], Supersaturation of Liquids with Gases, 762
Bailey (V. A.), Quantitative Theory of Interaction between Different Species of Animals, 524
Bain (A. D. N.), Younger Intrusive Rocks of the Kudaru Hills, Nigeria, 214
Bainbridge-Bell (L.), [R. A. Watson Watt and], Recording Wireless Echoes at the Transmitting Station, 657
Baker (E. S. Stuart), The Nidification of Birds of the Indian Empire, Vol. 1 (*Review*), 384
Baker (Prof. H. B.), Photochemical Reaction of Hydrogen and Chlorine, 27
Baker (Dr. J. F.), appointed professor of civil engineering in Bristol University, 848
Balbi (C. M. R.), Talking Pictures and Acoustics (*Review*), 188
Baldock (A. L.), [W. E. Cohen, A. G. Charles and], Chemical Composition of the Woods of the Ironbark Group of Eucalypts, 333
Baldwin (I. L.), [E. B. Fred, Elizabeth McCoy and], Root Nodule Bacteria and Leguminous Plants, 99
Ball (Sir Charles Arthur Kinahan), appointed Regius professor of surgery in Dublin University, 772
Ball (Dr. W. C.), [death], 866
Ballinger (Sir John), [death], 50
Balls (Dr. W. L.). Capacitance Hygroscopy, 329
Bamberger (Prof. E.), [death], 195
Bancroft (W. D.), and J. E. Rutzler, Jr., Agglomeration Theory of Sleep, 739
Banerjee (S.), [K. S. Krishnan and], Orientations of Molecules in the *p*-Benzoquinone Crystal, 653
Banerji (Prof. A. C.), Momentum and Energy in the Special Theory of Relativity, 517
Banerji (Prof. S. K.), and K. N. Sohoni, Hydraulic Seismographs, 547
Banks (C. A.), awarded the gold medal of Consolidated Gold Fields of South Africa, Ltd., 432
Banks (W. H.), [Dr. C. W. Davies and], Dissociation of Acetic Acid in Water, 328
Bannerman (W. B.), [death], 866
Bannister (F. A.), with chemical analyses by M. H. Hey, Identity of Mottramite and Psittacinite with Cupriferous Descloizite (Cuprodescloizite), 250
Barannikov (M. A.), Gypsy Art in Russia, 271
Barber (Dr. C. A.), [death], 298; [obituary article], 389
Barbey (Dr. A.), Les Insects Forestiers du Parc National Suisse, 234
Barbier (D.), [A. de La Baume Pluvinel and], Total Eclipse of the Sun on August 31, 1932, 922
Bardach (M.), [J. Basset, Mme. E. Wollman, M. A. Macheboeuf and], Biological Effects of Ultra-Pressures, 774
van Baren (Prof. J.), [death], 231; [obituary article], 390
Baring (Wing-Comdr. the Hon. Maurice), elected a member of the Athenæum Club, 510
Barker (A. H.), Electricity, Gas and other Fuels as Heating Agents, 32
Barker (Dr. S. G.), Fibres from the Coat of a Blackface Lamb, 799
Barkla (Prof. C. G.), Properties of X-Radiation, 166
Barlot (J.), A New Method of Analysis of Bituminous Schists, 774
Barnes (Col. F. P.), Mechanical Transport in India, 578
Baroni (A.), Diselenomesoxanilides and Oxyselenanilides, 107; Lithium Alloys (1), 71; Protoselenosulphochloride, 483
Barrell [Rolt and], Sources of Light for Interferometer Work, 244; [J. E. Sears and], A New Apparatus for Determining the Relationship between Wave-Lengths of Light and the Fundamental Standards of Length, 192
Barringer (D. M.), Meteor Crater, Arizona, 579.
Barritt (J.), Methionine in Wool, 689
Barrow (W.), elected pro-chancellor of Birmingham University, 336
Bartlett (Prof. F. C.), Remembering: a Study in Experimental and Social Psychology (*Review*), 309
Bartlett (R. W.), Co-operation in Marketing Dairy Products. 2 Parts (*Review*), 188
Barton (A. C.), Burial of a Bari Rain-maker, 29
Bary (P.), Causes of the Thixotropy of Certain Salts, 338
Basedow (Dr. H.), [obituary article], 865
Basset (J.), and M. A. Macheboeuf, Biological Effects of Ultra-Pressures, 251; Mme. E. Wollman, M. A. Macheboeuf and M. Bardach, Biological Effects of Ultra-Pressures, 774
Bateman (Prof. H.), Variation Problems for a Symmetrical Region, 472
Bates (Dr. L. F.), and B. J. Lloyd Evans, A Compact Electromagnet for General Purposes, 558
Bates (G. H.), Eradication of the Stinging Nettle, 208
Bather (Dr. F. A.), A Peculiar Visual Experience, 62; awarded the Mary Clark Thompson medal of the National Academy of Sciences, Washington, 304; re-elected president of the Palæontographical Society, 649
Baubiac (J.), [E. Crausse and], Modification of the Chronophotographic Method and some Applications, 482; Transitory Regimes, 559
Baudiš (Prof. J.), [obituary article], 830
Bauerman (Hilary), centenary of the birth of, 355
Baur (Dr. E.), elected a foreign member of the Linnean Society of London, 759
Bavink (B.), translated, with additional notes and bibliography, by H. S. Hatfield, The Anatomy of Modern Science: an Introduction to the Scientific Philosophy of To-day (*Review*), 707
Baxter and Alter, Lead from Cyrtolite, 881
Bayard-Duclaux (Mme. F.), Methods for putting in Circuit Specimens of Rock for Measuring their Electrical Resistance, 887
Baylis (Dr. H. A.), Worms Parasitic in Cetacea, 551
Beach (late A. C. G.), Talbot's Bands, 702
Beadles (C. F.), [death], 86; [obituary article], 122
Beal (Dr.), Aluminium in Foodstuffs, 432
Bean (Prof. R. B.), The Races of Man: Differentiation and Dispersal of Man (*Review*), 712
Beasley (H. G.), Hawaiian Feather Cape, 171
Beattie (Prof. J. M.), Prof. R. Donaldson, 122
Beatty (Dr. R. T.), Hearing in Man and Animals (*Review*), 147
Beauverie (J.), and Mlle. S. Monchal, Life of Green Plants in a Confined Atmosphere, 36

Bechterev (Prof. V. N.), translated by Emma and W. Murphy, General Principles of Human Reflexology: an Introduction to the Objective Study of Personality (*Review*), 675

Beck (Conrad), elected president of the Royal Microscopical Society, 128

Beckett (H. E.), 'Raw' Weather, 132

Beckley (V. A.), and F. McNaughtan, Distribution of Nitrates in the Soil and Root Development in Coffee, 878

Beckstrom (R. C.), Petroleum Production in Russia, 541

Beddington (R.), elected president of the Freshwater Biological Association, 796

Bedel (C.), Magnetic Susceptibility of Ferro-Silicons Rich in Silicon, 375

Beebe (Dr. W.), Deep Sea Dives in the Bathysphere, etc., 776

Bell (A. H.), The Exponential and Hyperbolic Functions and their Applications (*Review*), 319

Bell (Prof. E. T.), The Queen of the Sciences (*Review*), 319

Bell (Dr. G. D. H.), appointed University demonstrator in agricultural biology in Cambridge University, 920

Bell (G. E.), [Dr. G. W. C. Kaye and], Measurement of X-Ray Tube Current and Voltage, 552

Bell (Mary), and S. E. Green, Radiometer Action and the Pressure of Radiation, 374

Belling (Dr. J.), [death], 390; [obituary article], 575

Benedict (W. S.), [Dr. L. Harris, G. W. King and], Form and Vibrational Frequencies of the NO_2 Molecule, 621

Bennett (Dr. I.), The Practical Treatment of Diabetes (*Review*), 9

Berger (P.), [G. Tiercy and], Aerological Soundings and the Wind Gradient in Switzerland, 143

Bergmann (Prof. M.), Amino-Acids, Proteins and Proteolytic Enzymes, 662, 698

Berkeley (C.), Oxidase of the Crystalline Style, 94

Berliner (Dr. Arnold), Seventieth birthday of, 127

Bernacchi (Commdr. L. C.), A Very Gallant Gentleman (*Review*), 782

Bernal (J. D.), and D. Crowfoot, Crystal Structure of Vitamin B_1 and of Adenine Hydrochloride, 911

Bernard (P. N.), and J. Guillerm, Transmissible Lysis of the Cholera Vibrion, 887

Bernatzik (Dr. H. A.), mit einem beitrag von B. Struck, Äthiopen des Westens: Forschungsreisen in Portugiesisch-Guinea, Band 1 und 2 (*Review*), 599

Bertholf (Prof. Ll. M.), Eyes and Colour Change, 331

Berthon (R.), Heats of Moistening Silica Gel with Various Liquids, 106

Bertrand (G.), and L. Silberstein, Importance of Sulphates as Manure, 215

Besicovitch (A. S.), Almost Periodic Functions (*Review*), 384

Betz [Volmar and], Emetic Derivatives of Lactic Acid, 410

Beutel and Kutzelnigg, Fluorescence of Zinc Oxide, 917

Bhattacharya (A. K.), [Prof. N. R. Dhar, B. L. Mukerji and], Kinetics of the Iodine-Oxalate Reaction, 840

Bickham (S. H.), bequest by, to Cambridge University, 884

Bierry (H.), B. Gouzon and Mlle. C. Magnan, Application of the Iodometric Method to the Estimation of Sugar in the Blood, 667

van Biesbroeck (Prof.), Comets, 245

Biot (M.), Critical torsional Oscillations of a Rotating Accelerated Shaft, 631

Biquard (P.), An Optical Method for the Measurement of the Absorption of Ultra-Sound Waves by Liquids, 375

Birch (T. W.), and Dr. W. J. Dann, Estimation and Distribution of Ascorbic Acid (Vitamin C) and Glutathione in Animal Tissues, 469; Dr. L. J. Harris and S. N. Ray, Hexuronic (Ascorbic) Acid as the Antiscorbutic Factor, and its Chemical Determination, 273

Bjerknes (Prof. V. F. K.), elected a foreign member of the Royal Society, 798

Black (F. A.), The Calendar and its Reform (*Review*), 859

Blackett (P. M. S.), appointed professor of physics at Birkbeck College, 480; Cosmic Radiation (Symons Memorial Lecture), 429; [Dr. J. Chadwick, G. Occhialini and], New Evidence for the Positive Electron, 473; and G. Occhialini, Photography of the Tracks of Penetrating Radiation, 286; Wilson Photographs of Cosmic Ray Phenomena, 589

Blacktin (Dr. S. C.), Interaction between Soot Films and Oil, 873

Blackwelder (Prof. E.), Age of Meteor Crater, 404

Blaringhem (L.), A Case of Atavism in a Strain of the Opium Poppy, 178

Blatchford (A. H.), Diffraction of X-Rays by Liquid Sulphur, 813

Blau (Marietta), and Hertha Wambacher, Photographic Detection of Protons Liberated by Neutrons (2), 287

Bledisloe (Lord), Economic Value of Agricultural Science, 197

Bliss (E. W.), Tabulation of World Weather (5), 35

Boardman (E. M.), [E. T. Burton and], Effects of Solar Eclipse on Audio Frequency Atmospherics, 81

Bloch (A. M.), [D. M. Newitt and], Slow Combustion of Ethane at High Pressures, 214

Boas (Prof. F.), Aims of Anthropological Research, 196

Bobrovnikoff (N. T.), Halley's Comet in its Apparition of 1909–1911, 282

Bocking (T. G.), Magnetic Data and Mine Surveying, 768

Boggio (T.), Curvature of Lines of Varieties, 71

Bohr (Prof. N.), Light and Life, 421; 457

Bolam (Dr. T. R.), The Donnan Equilibria: and their Application to Chemical, Physiological and Technical Processes (*Review*), 859

Boman (late Dr. E.), Archæological Researches in the Argentine, 63

Bond (Dr. W. N.), Numerical Examples in Physics (*Review*), 320

Bone (Prof. W. A.), awarded the medal of the Society of Chemical Industry; the work of, 793; Photographic Analysis of Explosion Flames, 300; Researches on Gaseous Combustion (Bakerian Lecture), 494; and others, Gaseous Combustion at High Pressures, 245

Bonner (J.), [K. V. Thimann and], Growth Hormone of Plants (2), 631

Bonot (A.), Modification of the Seric Proteins Isolated by the Acetone Method and Myxoprotein, 106

Boratynski (K.), and A. Nowakowski, Modifications of Phosphoric Anhydride, 595

Bordier (H.), Production of Merget's Phenomenon by d'Arsonvalisation with Short Waves, 375

Boring (Dr. Alice M.), C. C. Liu and S. C. Chou, Handbook of North China Amphibia and Reptiles, 304

Borradaile (L. A.), and F. A. Potts. With chapters by Prof. L. E. S. Eastham and J. T. Saunders, The Invertebrata: a Manual for the use of Students (*Review*), 76

van den Bos (W. H.), Measures of Double Stars at the Union Observatory, Johannesburg, 476

Bossolasco (M.), Magnetic Measurements at Mogadiscio, 560

Bossuet (R.), Examination of Minerals for the Alkali Metals, 923; Photographic Sensibility of the Lines of the Alkaline Metals in the Oxyacetylene Flame, 482

Bostock (Dr. J.), The Neural Energy Constant: a Study of the Bases of Consciousness (*Review*), 80

Boswell (Prof. P. G. H.), [Dr. L. S. B. Leakey, Prof. H. Reck, A. T. Hopwood, Dr. J. D. Solomon and], The Oldoway Human Skeleton, 397

Bottoni (O.), Relationships between the Chemical Composition of the Soil and that of its Colloidal Contents, 560

Boulton (Prof. W. S.) the title of emeritus professor conferred upon, 336

Bouquet (Rev. A. C.), A Study of the Ordinary Arguments for the Existence and Nature of God; Religious Experience; its Nature, Types and Validity; Phases of the Christian Church: a Short View of its History (*Review*), 677

Bourdon (B.), and others, A History of Psychology in Autobiography. Vol. 2 (*Review*), 321
Bourne (G.), Vitamin C in the Adrenal Gland, 874
Bourne (Prof. G. C.), [death], 390; [obituary article], 496
Boutaric (A.), [C. Achard and], Suspensions prepared starting with Proteins separated from Serum, 178; and Mlle. Madeleine Roy, Influence of Radio-Active Radiations on the Flocculation of Colloids, 738
Boutry (G. A.), [P. Fleury and], Exact Measurement of Photographic Densities, 738
Bowden (Dr. F. P.), S. D. D. Morris and Dr. C. P. Snow, Absorption Spectrum of Vitamin A at Low Temperatures, 582
Bowden (Dr. P.), and T. Moore, Absorption Spectrum of the Vitamin E Fraction of Wheat-Germ Oil, 512
Bower (S. Morris), Summer Thunderstorms, 473
Bower (W. R.), and Prof. R. Satterly, Practical Physics. Third edition (*Review*), 491
Bowles (E. O.), [W. B. Marshall and] New Fossil Fresh Water Molluscs from Ecuador, 589
Bowser (W. E.), and J. D. Newton, Effect of Weed-killers on the Soil, 880
Boycott (Prof. A. E.), Local Lists of Animals, 94
Boyle (C.), and J. J. Ryan, Grass Silage, 410
Boys (Dr. C. V.), A Destructive Lightning Flash, 765; Progressive Lightning: a New Stereoscope, 492
Bracewell (S.), [A. Brammall and], Garnet in the Dartmoor Granite, 250
Brackett (F. S.), and E. S. Johnstone, Functions of Radiation in the Physiology of Plants, 331
Braddick (Dr. H. J. J.), and Prof. R. W. Ditchburn, Absorption of Light in Cæsium Vapour, 132
Bradfield (A. E.), A. R. Penfold and J. L. Simonsen, Essential Oil from the Wood of *Eremophila Mitchelli*, 667
Bradley (A. J.), and A. H. Jay, Quartz as a Standard for Accurate Lattice-Spacing Measurements, 813; and Phyllis Jones, X-Ray Investigation of the Copper-Aluminium Alloys, 589
Bradley (H.), Physics in the Boot and Shoe Industry, 756
Bragg (Sir William), Old Trades and New Knowledge (*Review*), 860; *presentation of a Portrait of, to the Royal Institution*, 647; The Crystals of the Living Body, 125; The World of Sound (*Review*), 860
Bragg (Prof. W. L.), Structure of Alloys, 749
Brailsford (Dr. J. F.), appointed radiological demonstrator in anatomy in Birmingham University, 248
Brammall (A.), and S. Bracewell, Garnet in the Dartmoor Granite, 250
Brandt (L.), Yangtse-Kiang Flood of 1931, 280
Brata (Luang), [Dr. C. F. Powell and], Positive Ion Emission from Oxide Catalysts, 168
Brazier (C. E.), and L. Génaux, The Earthquake of March 2, 1933, 596
Bricout (P.), A Magnetic Apparatus for the Determination of Thicknesses, 595
Bridgman (Prof. P. W.), High Pressure Research, 280; The Physics of High Pressure (*Review*), 259
Brierley (Prof. W. B.), elected president of the Association of Economic Biologists, 304
Briers (C. T.), Fauna of Hot Springs in North America, 403
Briggs (Prof. H.), [Prof. P. F. Kendall and], Formation of Rock Joints and the Cleat of Coal, 922
Briggs (Dr. L. J.), appointed director of the U. S. Bureau of Standards, 580
Brightman (R.), The Cost of a New World Order (*Review*), 183
Brillouin (M.), Linear Partial Differential Equations in the Plane, 410
Bristowe (W. S.), Insect-Eating in Siam, 234
British Drug Houses, Ltd., Guide to the B.P., 1932, 128
Broadhurst (E.), and J. D. Campbell, Geology and Petrology of the Mount Leinster District, North-East Victoria, 703
Brock (G. C.), A Method of Preparing a Filter for the 3130 Mercury Line, 410
Brooklehurst (Prof. R. J.), Neuro Humoral Mechanisms, 65
Brockway (L. O.), and L. Pauling, Determination of the Structures of the Hexafluorides of Sulphur, Selenium and Tellurium by the Electron Diffraction Method, 739
van den Broek (Prof. J. A.), Elastic Energy Theory (*Review*), 347
de Broglie (Prof. L.), Théorie de la quantification dans la nouvelle mécanique (*Review*), 639
Broniewski (W.), and S. Jaslan, Influence of Oxygen on the Properties of Copper, 338
Brooks (Dr. C. E. P.), Climate: a Handbook for Business Men, Students and Travellers. Second edition (*Review*), 9; and Theresa M. Hunt, Variations of Wind Direction in the British Isles since 1341, 814
Brooks (Harriet), (Mrs. Frank Pitcher), [obituary article], 865
Brooks (Matilda Moldenhauer), Penetration of *m*-Bromophenol Indophenol and of Guaiacol Indophenol into *Valonia Ventricosa*, 631
Brotherton (C. R.), Gift to Leeds University, 665
Brown (F. J.), Life-History of the Fowl Tapeworm, *Davainea proglottina*, 276
Brown (Prof. J. Macmillan), Education and Economic Recovery, 538
Brown (R.), Nitrogen Fixation in the Genus *Lolium*, 169
Brown (Prof. W. Langdon), elected a member of the Athenæum Club, 510
Browne (W. M.), Photographing the Moon's Shadow on the Earth, 697
Browne (W. R.), Possible Correlation of certain Pre-Cambrian Granites of Australia and some Deductions Therefrom, 667
Bruhat (G.), and A. Guinier, Improvement of the Photo-electric Polarimeter, 630
Brunt (D.), Adiabatic Lapse-Rate for Dry and Saturated Air, 814
Bryce (J.), Economic Possibilities of Rice Grass, 368
Bryce (Prof. T. H.), [N. H. W. Maclaren and], Early Stages in the Development of Cavia, 922
Brydon (H. B.), Canals on Mars, 518
Buch (K.), Boric Acid in Sea Water and its Effect on the Carbon Dioxide Equilibrium, 688
Buck (Dr. P. H.), (Te Rangi Hiroa), Ethnology of Manihiki and Rakahanga, Cook Islands, 588
Buckley and Snyder, Spreading of Liquids on Solid Surfaces, 407
Bugnard (L.), P. Gley and A. Langevin, Recording and Measurement of the Blood Pressure, 375
Bullen (K. E.), [Dr. H. Jeffreys and], Corrections to the Times of the *P* Wave in Earthquakes, 97
Bunker (J. W. M.), [R. S. Harris and], Bacterial Detoxification, 244
Burch (F. P.), [obituary article], 390
Burden (Mrs. R. G.), Gift for Research into Mental Problems and Disorders, 159
Buret (R.), [C. Dufraisse and], The Dissociable Organic Oxides, 70
Burge (W. S.), Power Station Efficiency, 518
Burger (Dr. H. C.), [Dr. L. S. Ornstein, Dr. W. J. H. Moll and], Objektive Spektralphotometrie (*Review*), 824
Burgers (Dr. W. G.), Recrystallisation Power and Shear Hardening in Aluminium Single Crystals, 326
Burgevin (H.), Nitrogenous Manuring of Legumes, 660
Burkitt (Prof. A. N. St. G. H.), elected president of the Linnean Society of N.S.W., 759
Burkitt (M. C.), Racial Distribution in Palæolithic Europe, 540; [E. J. Wayland and], Stone Age Culture in Uganda, 730
Burnell (Maisie), [H. E. Dadswell and], Identification of the Coloured Woods of the Genous *Eucalyptus*, 280

Alloys, Structure of, Prof. W. L. Bragg, 749
Alpha Particle, The Entry of the Disintegrating, into the Nitrogen Nucleus, etc., E. C. Pollard, 375
Aluminium: Alloys at High Temperatures, Fatigue-Resisting Properties of, J. W. Cuthbertson, 660; Alloys Containing Iron as a Model of the Electrolytic Purification of Molten Aluminium from Iron, Electrolysis of, R. Kremann and L. Lammermayer, 251; -Beryllium Alloys, Ageing of the, after Tempering, C. Matignon and J. Calvet, 886; Hydride, Band Spectrum of, Predissociation and Pressure Effects in the, Prof. E. Hulthén and R. Rydberg, 470; Hyperfine Structure in, R. Ritschl, 58; in Food-Stuffs, Dr. Beal, 432; Separation of Phosphoric, Arsenic and Vanadic Acids from, A. Travers and Lu, 595; Single Crystals, Recrystallisation Power and Shear Hardening in, Dr. W. G. Burgers, 326
American: Academy of Arts and Sciences, Award of the Rumford medal to Dr. H. Shapley, 871; Association, Election of Officers, 164; Prof. H. N. Russell elected president, and Prof. H. B. Ward elected permanent secretary; award of the American Association prize to Dr. H. Eyring, 304; Pronghorn increasing in numbers, 849
Amides, Colour and Structure of, Mme. Ramart-Lucas and Mlle. Wohl, 286
Amino-Acids, Proteins and Proteolytic Enzymes, Prof. M. Bergmann, 662; 698
Aminoazo-Compounds, Chemical Changes Involved in the Formation of the, J. C. Earl and N. F. Hall (2), 667

Ammonia, Aqueous Solution of, Photolysis of, L. Gion, 410
Ammonites, Phylogeny of, late J. Perrin Smith, 368
Amor, The Minor Planet, 476
Amphibia, Internal Ear of, C. Guareschi, 659
Amphibians and Fishes, Chromosomes of, Dr. S. Iriki, 659
Amphioxus, Nephridia of, Prof. E. S. Goodrich, 439
Analysts: Public, and the Food Industry, Dr. J. T. Dunn (*Review*), 822; Society of Public, and other Analytical Chemists, Dr. B. Dyer and Dr. C. A. Mitchell (*Review*), 822
Ancestor Spirits among the Nuba, D. Hawksworth, 403
Ancient Monuments of England, The, Sir Charles Peers, 253
Andalusite Twin, An, P. Aloisi, 851
Andaman and Nicobar Islands, Census Report, 199
Andes in Ecuador, Age of the, 589
Angiosperms, Origin of, Prof. G. R. Wieland, 360
Animal: Growth, Heterogony and the Chemical Ground-Plan of, C. H. Waddington, 134; Life, Components of the Atmosphere, and Synthetic Gases in Relation to, Prof. J. W. Hershey, 238; Lore in English Literature, Dr. P. A. Robin (*Review*), 257; Myths (*Review*), 257
Animals, Vertebrate, Collecting and Preserving, Methods of, R. M. Anderson, 906
Ankole, South-West, and Adjacent Territories, Geology of, A. D. Combe, A. W. Groves and W. C. Simmons, 172
Annuaire Astronomique Camille Flammarion, 1933, 369
Annual Register, The, 1932, Edited by Dr. M. Epstein (*Review*), 824
Annuario del Observatorio Astronomico de Madrid, 1933, 405
Anode Spot in a Neon Tube, Dr. T. Takamine, T. Suga and A. Yanagihara, 584
Antarctic: Australian Sector in the, 577; British Claims in the, 270; Geology and Glaciation, 847
Antennal Secretion in Insecta, S. Maulik, 516
Anthropological: and Ethnological Sciences, International Congress of, 719; Fieldwork, Aeroplane and Camera in (*Review*), 599; Research, Aims of, Prof. F. Boas, 196; Teaching and Research in, Prof. R. Firth, 540
Anthropology, Early Publication in, 53
Anticyclones, Intrusion of Air into, C. S. Durst, 737
Antimony: Iodide, Precipitation of, and its Hydrolysis, F. François, 923; Molecular Fluorescence of, Jean Genard, 132; Poisoning from Enamelled Vessels, 915
Anti-Veterinary Propaganda, 90
Aphanapteryx, The Dodo and the, G. Renshaw, 728
Aphids, Time of Embryonic Segregation in, A. F. Shull, 775
Apples, Colour of, Improvement of, H. Goude, 331
April Showers, 481
Aquaria, 270
Aquatic Insect Larvæ, Tracheal and Blood Gills in, Dr. W. H. Thorpe, 549
Aqueous: Electrolytes, Determination of the Dielectric Constants of, Application of the Resonance Method to the, M. Jezewski, 448; Solutions, Viscosity of, Grinnell Jones and S. K. Talley, 475
Archaic Tracks Round Cambridge, A. Watkins (*Review*), 491
Archæological Exploration in Oaxaca, Mexico, Miss Emma Reh, 509
Archæology: and Folk-Tradition, Prof. H. J. Fleure, 431; Ethics and, 561
Archimedean Bodies in Spaces of Several Dimensions, K. Klemenz, 703
Architectural Graphic Standards: for Architects, Engineers, Decorators, Builders and Draftsmen, C. G. Ramsey and H. R. Sleeper (*Review*), 224
Arctic Ice passes Cape Farewell, 105
Argentine, Archæological Researches in the, late Dr. E. Boman, 63
Aristogenesis, Prof. H. F. Osborn, 768
Armstrong College, Report for 1931–32 of the Standing Committee for Research, 920
Arsenic, Nuclear Moment of, M. F. Crawford and A. M. Crooker, 655
Arsenolite and Senarmontite, Orientation of, by Mica, R. Hocart, 851
Arts in Industry, The, 73
Ascaphus, The 'Tail' of the Male American Toad, Prof. C. G. S. de Villiers, 692
Ascorbic Acid: Prof. A. Szent-Györgyi and Prof. W. N. Haworth, 24; Constitution of, Dr. E. L. Hirst, E. G. V. Percival and F. Smith, 617; Vitamin C and, A. L. Bacharach, 364; Estimation and Distribution of, and Glutathione in Animal Tissues, T. W. Birch and Dr. W. J. Dann, 469
Asia: Central, Research in, 705; Innermost (*Review*), 415; South-East, Prehistory of, Dr. F. Sarasin, 879
Ashmolean, The Old: Oxford, T. E. James, 716; The 250th Anniversary of, 793
Asparagus Growing, Bulletin on, 722
Aspergillin: The Pigment of the Spores of *Aspergillus niger*, A. Quilico and A. di Capua, (1), 851, (2), 924
Aspergillus niger, Action of Certain Alkaloids on the Development of, G. Mezzadroli and A. Amati, 339
Astrolabes: (*Review*), 819; of the World, The, Dr. R. T. Gunther. 2 vols. (*Review*), 819
Astronomical: Notes for January, 31; February, 137; March, 281; April, 476; May, 625; June, 769; Radiative Stability, The: Sir Joseph Larmor, 805; Dr. G. C. Simpson, 875
Astronomy, Observational and Theoretical, Prof. H. H. Plaskett, 648
Athenæum Club, Election to: Dr. S. Courtauld, E. G. V. Knox and Dr. N. V. Sidgwick, 200; Wing-Commdr. the Hon. Maurice Baring, Prof. W. Langdon Brown and Prof. H. H. Dodwell, 510
Äthiopen des Westens: Forschungsreisen in Portugiesisch-Guinea, Dr. H. A. Bernatzik. Band 1 und 2 (*Review*), 599
Atlantic Ocean: Southern, Life in the, 34; South-West Influence of the Pacific on the Circulation in the, A. J. Clowes, 189
Atmosphere: Components of the, and Synthetic Gases in Relation to Animal Life, Prof. J. W. Hershey, 238; in the Lyons Region, Transparency of the, P. Flagolet, 339
Atmospheric: Ionisation, Influence of Condensation Nuclei and Dust Particles on, Prof. P. J. Nolan, 922; Ions, Relations between the Combination Coefficients of, F. J. W. Whipple, 522; Ozone, Estimation of, by Visual Photometry, J. Gauzit, 36; Pollution, Investigation of, 758
Atmospherics in Australia, G. H. Munro and L. G. H. Huxley, 592
Atom: The Interpretation of the, Prof. F. Soddy (*Review*), 4; Properties of the, Prof. G. Hevesy (*Review*), 4
Atomic: and Molecular Forces of Chemical and Physical Interaction in Liquids and Gases, and their Effects, Prof. R. D. Kleeman (*Review*), 80; Charge, Determination of, Early History of the, 569; Disintegration with Emission of Neutrons, G. Kirsch and R. Trattner, 852; Number Zero, The New Element of, the Neutron and Neuton, Prof. W. D. Harkins, 23; Physics, Recent Advances in, Prof. G. Castelfranchi. Translated by Dr. W. S. Stiles and Dr. J. W. T. Walsh. 2 vols. (*Review*), 319; Weights, International, 405
Atoms, Molecules and the Atmosphere, Prof. S. Chapman, 271
Atriplex vesicarium, Growth and Reaction to Grazing of the Perennial Saltbush, T. G. B. Osborn, J. G. Wood and T. B. Paltridge, 631
Audio Frequency Atmospherics, Effects of Solar Eclipse on, E. T. Burton and E. M. Boardman, 81
Auroras, Low, Dr. G. C. Simpson, 828
Australia: Anthropological Teaching and Research in, Prof. R. Firth, 540; Atmospherics in, G. H. Munro and L. G. H. Huxley, 592; The Cultural and Racial Clash in, Dr. A. P. Elkin, 520; Improvement of Beef Cattle in, 576; Possible Correlation of Certain Pre-Cambrian Granites of, W. R. Browne, 667; Prickly Pear in, Eradication of, 613

Australian: Dairy Cattle Research Council, 356; Entomology, Bibliography of, 1775–1930, 466; Hesperiidæ, G. A. Waterhouse (3), 631; Opals, β-Cristobalite in, Occurrence of, F. P. Dwyer and D. P. Mellor, 524; Timbers, Chemistry of, 333; Water Supply, Dr. J. P. Thomson, 797
Autogiro, New, 646
Avitaminosis and Intoxication, M. Mitolo (1), 411; (2), 484

β-Rays: Relation between the Absorption of, by Organic Compounds and the Molecular Structure of the Latter, G. Fournier and M. Guillot, 447; Absorption of the, by Matter, G. Fournier and M. Guillot, 179
B. salmonicida in River Waters, Presence of a Bacteriophage for, Dr. C. Todd, 360
Bacon: Francis, a Biography, Mary Sturt (*Review*), 490
Bacterial: Detoxification, R. S. Harris and J. W. M. Bunker, 244; Growth Curve, The, and the History of Species, Dr. A. S. Corbet, 61; Proteases, Influence of Hydrocyanic Acid on, G. Gorbach and A. Schonbeck, 287
von Baeyer, Adolf, als Lehrer und Forscher, Prof. H. Rupe, 294
Bananas, Hybrid, E. E. Cheeseman, 552
Band Spectra which appear near Visible Triplet Lines of Mercury, E. Matuyama, 58
Baltic, Inertia Currents in the, T. Gustafson and B. Kullenberg, 586
Bari Rain-Maker, Burial of a, A. C. Barton, 29
B Vitamins, Rôle of the, in the Utilisation of the Glycides by the Organism of the Pigeon, R. Lecoq, 630
Barium: Azide, Acceleration of the Decomposition of Crystals of, by the Emission from Radium Emanation, Prof. W. E. Garner and C. H. Moon, 513; Oxide (BaO), Band Spectra of, P. C. Mahanti, 402
Barley: 409; Egyptian Neolithic, A. Jackson, 652
Barnacles, Young, Change their Coats, 594
Barracuda Fisheries, 773
Bast-Sap, Prof. H. H. Dixon, 367
Batholiths and Ore Deposits, Prof. W. H. Emmons, 730
Bathysphere, Deep Sea Dives in the, Dr. W. Beebe, 776
Battersea Power Station, T. V. Robinson, 720
Bau der Erde, Der, und die Bewegungen ihrer Oberfläche: eine Einführung in der Grundfragen der allgemeinen Geologie, Prof. W. von Seidlitz (*Review*), 318
Bauxite and Aluminous Laterite, Dr. C. S. Fox. Second edition (*Review*), 347
'Bayoud', a Disease of the Date Palm, Etiology of, R. Maire, E. Foëx and G. Malençon, 922
Bechuanaland, Chastity in, Dr. I. Shapera, 516
B.D.H.: Guide to the B.P. 1932, 128; Products, 834
Belfast University, Dr. K. G. Emeléus appointed professor of experimental physics, 628
Belgrade, University of, Observatory of the, *Annuaire* of the, for 1933, 518
Bengali Chemist, Life and Experiences of a, Sir Prafulla Chandra Rây (*Review*), 672
Bentham's Theory of Fictions, C. K. Ogden (*Review*), 152
Benzene, Slow Combustion of, J. Amiel, 774
p-Benzoquinone Crystal, Orientations of Molecules in the, K. S. Krishnan and S. Banerjee, 653
Beriberi, Mechanism of Sudden Heart-Failure in Cases of, K. F. Wenckebach, 251
Berkeley, Prof. G. Dawes Hicks (*Review*), 322
Bērūnī, Das Vorwort zur Drogenkunde des. Eingeleitet, übersetzt und erlautert von M. Meyerhof (*Review*), 491
Beryllium and Helium, Lord Rayleigh, 724
Bessemer gold medal of the Iron and Steel Institute, Award of the, to Dr. W. H. Hatfield, 236
Bezssonoff's Reaction for the *C* Factor, Nature and Value of, A. Salvatori, 339
Bildtelegraphie und des Fernsehens, Handbuch der: Grundlagen, Entwicklungsziele und Grenzen der elektrischen Bildfernübertragung. Bearbeitet und herausgegeben von Prof. F. Schröter (*Review*), 781
Binary Alloys, Constitution of, at Room Temperature, Prof. A. N. Campbell, 438
Biochemistry, Researches in, Prof. A. Stoll, 541
Biographical Fragments, Sir Arthur Schuster (*Review*), 75
Biology: and Philosophy (*Review*), 529; Teaching of, W. B. Yapp, 203
Biology's Message for Civilisation, Prof. H. B. Fantham, 197
Biotechnology, 597
Bird: Life on Ailsa Craig, 903; Migration, Prof. W. Rowan (3), 288; in Tropical Africa, J. P. Chapin, 331
Birds: Courtship of, 392; Frequency of, 885; Migration and Plumage Coloration of, 921; Movements of Winter Flocks of, 69; New Zealand, The Life Histories of, E. F. Stead (*Review*), 603; of Suffolk, A History of the, Dr. C. B. Ticehurst (*Review*), 568; of the Indian Empire, The Nidification of, E. C. Stuart Baker. Vol. 1 (*Review*), 384; of the Russian Altai and North-West Mongolia, Distribution of, late P. Sushkin, 551; Summer Visiting, Immigration of, 481; Wild, Protection of, 337; Winter Congregations of, 69; Winter Territory Amongst, J. B. Price, 730
Birmingham University: appointment of Dr. J. F. Brailsford as radiological demonstrator in anatomy and W. J. Rees as temporary assistant lecturer in botany, 248; W. Barrow elected pro-chancellor; conferment of title of emeritus professor on Prof. W. S. Boulton and Prof. J. T. J. Morrison, 336; Foundation of a Poynting lecture, 736
Birthday Honours, King's, 830
Birth Control Association, National, Annual Report of the, 271
Bitumen in Embalming, Dr. P. E. Spielmann, 588
Bituminous Schists, A New Method of Analysis of, J. Barlot, 774
Blackboard Coloured Diagrams: Biological Series, *Rana temporaria*, 3 parts (*Review*), 786
Blackthorn Winter, The, 445
Blood: Pigments of the Invertebrates, Molecular Weights of the, Prof. The Svedberg and Astrid Hedenius, 325; Pressure, Recording and Measurement of the, L. Bugnard, P. Gley and A. Langevin, 375; -Vessels, Disposal of Debris by, Drs. E. R. and E. L. Clark, 880
Botany in Russia, 554
Bond's Numerical Examples in Physics, concerning the review of, Lord Holden, 467
Boric Acid in Sea Water and its Effect on the Carbon Dioxide Equilibrium, K. Buch, 688
Boron: Hydrides, Electrolysis of, A. Stock and E. Wiborg, 212; Structure of the *K* Line of, A. Hautot, 595
'Borrowed Days', The: 445; Sir Herbert Maxwell, Bt., 515
Botanical Analyses of Grasslands, Two Forms of Sampler used in Estimating the number of Plants per Acre in, M. J. Gorman, 410
Brachiopod Genera of the Sub-Orders Orthoidea and Pentameroidea, Dr. C. Schuchert and G. A. Cooper, 244
Brazil Nuts, Barium as a Normal Constituent of, W. M. Seaber, 814
Brazilian Meteorological Service, Retirement of R. P. Xavier as director; Appointment of C. de A. Martins Costa, 581
Bridges, Early American, Evolution of, Capt. L. N. Edwards, 429
Bristol: District, Geology of the, Prof. S. H. Reynolds, 65; University: bequest to, by J. W. White, 299; Report for 1931–32, 665; Dr. R. W. Gurney appointed a research fellow, 772; Dr. J. F. Baker appointed professor of civil engineering, Prof. A. E. Trueman professor of geology, Prof. G. Hadfield professor of pathology, J. W. de Witt G. Thornton lecturer in pharmacology, J. D. A. Gray senior pathological officer, and J. W. Edgell dairy bacteriologist, 848

British: Architects, Royal Institute of: award of the Royal gold medal of the, to Sir Charles Peers, 236; 497; Army, Health of the, during 1931, Lieut.-Gen. Fawcus, 509; Association: Installation of Sir Frederick Gowland Hopkins as president, 50; Leicester meeting of the, 680; Mathematical Tables. Vol. 1: Circular and Hyperbolic Functions, Exponential Sine and Cosine Integrals, Factorial (Gamma) and Derived Functions, Integrals of Probability Integral. Prepared by the Committee for the Calculation of Mathematical Tables. Vol. 2: Emden Functions: Being Solutions of Emden's Equation, together with Certain Associated Functions (*Review*), 318; Coals, A. L. Curtis, 580; County Flora (*Review*), 309; Electrical and Allied Industries Association, Annual Report of the, 267; Forestry, Problems of, Prof. R. S. Troup, 900; Geographers, Institute of, Election of officers, 51; Industries Fair: 87; Scientific Instrument Section, 139; Marine Mollusca, The, R. Winckworth, 334; Museum: Sir Charles Reed Peers appointed a trustee of the, 164; (Natural History): Acquisitions at the, 163; 301; 464, 465; 795; Catalogue of the Pontian Carnivora of Europe in the Department of Geology, Dr. G. E. Pilgrim (*Review*), 454; Ornithologists' Union, Dr. W. Stone elected an honorary member of the, 723; Polar Year Expedition, Report of, J. M. Stagg, 464; Science Guild Research and Development Lecture, 124; Solomon Islands: Early History of the, R. J. A. W. Lever, 587; Protectorate, H. T. Pagden appointed entomologist to the, 687; Zoologists, Association of, Annual Meeting of the, 88
Broadcasting, Empire, 16; 160
Bromine: -Hydrogen and Bromine-Carbon Dioxide, Measurement of the Diffusion Coefficients of, J. E. Mackenzie and H. W. Melville, 250; Spectra of, Br V, VII and IV, A. S. Rao and Dr. K. R. Rao, 170
Brush-Turkeys, Nest-Building of, 233
'Buchan Cold-Spell': The First, 177; Second, 521; Third, the Ice Saints, 665; Fourth, 921
Buff's Compound, Complex Anion of, and of Bunsen's Salt, F. Holzl and W. Stockmair, 251
Bufumbira, The Volcanic Area of, Part 1: The Geology of the Volcanic Area of Bufumbira, South-West Uganda; with notes on the Petrology and Economic Geology, A. D. Combe and W. C. Simmons (*Review*), 821
'Bull-Dog' Calf in African Cattle, J. Carmichael, 878
Bull Frogs Calling, 629
Bunsen Society, Prof. F. G. Donnan elected an honorary member of the, 871
Burmese Spirit-World, Maung Htin Aung, 767
Business Rationalisation, its Dangers and Advantages considered from the Psychological and Social Standpoints, Dr. C. S. Myers (*Review*), 567
Butterflies, Preying of Birds on, Effect of, C. L. Collenette, 200
Butters, Australian, New Zealand and English, Vitamin Content of, M. E. F. Crawford, E. O. V. Perry and Dr. S. S. Zilva, 770
Butyl Alcohol, Catalytic Dehydration of, by Alumina, Causes of the Simultaneous Production of 1-Butene and 2-Butene in the Course of the, C. Matignon, H. Moureu and M. Dodé, 738

Cabbages and related Green Crops, 21
Cacao Research at the Imperial College of Tropical Agriculture, 580
Cadmium Hydride, Isotope Effect in the Spectrum of, E. Svensson, 28
Cahn Hill-Improvement Scheme, Wales, M. Griffiths appointed lands director, 720
Calanus: *finmarchicus*, Life History of, 843; Metamorphosis of, 105
Calcite, Periodicity in the Solarisation of, S. Iimori, 619
Calcium: Isotope with Mass 41 and the Radioactive Half-Period of Potassium, Prof. J. Kendall, W. W. Smith and T. Tait, 688; Phosphate, Palæozoic Deposits of, Rôle of the Trilobites in the Genesis of the, L. Cayeux, 850
Calculating Machine, An Electrical, R. M. Mallock, 880
Calculus of Variations, Characterisation of Fields in the, M. Morse and S. B. Littauer, 631
Calendar: of Nature Topics, 17, 34, 69, 105, 141, 177, 213, 248, 284, 337, 373, 409, 445, 481, 521, 557, 594, 629, 665, 701, 737, 773, 812, 849, 885, 921; The, and its Reform, F. A. Black (*Review*), 859
California Ground Squirrel Control Program, E. S. Kellogg, 721
Californian Earthquake of March 10, H. O. Wood and C. F. Richter, 686
Cambial Activity, Prof. J. H. Priestley, Lorna I. Scott and Marjorie E. Malins, 375
Cambridge University: Dr. G. Salt elected Stringer fellow at King's College, 141; Opening of the Royal Society Mond Laboratory, 210; Dr. H. Spencer Jones elected an honorary fellow of Jesus College, 213; gift to the Molteno Institute of Parasitology by the Rockefeller Foundation; gift by the Goldsmiths' Company; award of the Gordon Wigan prize for chemistry to T. P. Hoar, 284; award of the Balfour studentship in biology to F. R. Parrington, 336; Dr. N. J. T. M. Needham appointed Sir William Dunn reader in biochemistry; V. J. Chapman elected Frank Smart student in botany; E. A. Maxwell and R. H. Stoy awarded Smith's prizes; W. E. Candler, C. Strachan and M. H. H. Walters awarded Rayleigh prizes, 408; gift by W. J. Courtauld, 444; A. G. D. Watson and E. S. Shire elected fellows of King's College, 593; W. V. Lewis appointed University demonstrator in geography, and Dr. N. W. Pirie University demonstrator in biochemistry, 628; Dr. M. Dixon appointed University lecturer in biochemistry; Dr. E. G. Holmes University lecturer in place of Dr. M. Dixon; A. D. Thackeray elected Sheepshanks exhibitioner, 665; bequest by F. E. Elmore; gift by J. E. Little, 700; award of the Adams prize to A. H. Wilson; grants made from the Balfour fund to C. Forster Cooper and I. T. Sanderson; Dr. F. R. Winton recommended for the readership in physiology; H. McC. Taylor elected a research fellow of Clare College, 736; award of the Raymond Horton-Smith prize to Dr. J. E. Semple, 772; Dr. R. O. Redman appointed University lecturer in astrophysics; J. A. Ratcliffe University lecturer in physics; Dr. N. Feather and P. I. Dee University demonstrators in physics; proposed foundation of a studentship in human anatomy and a readership in pharmacology under the Shield bequest, 811; R. F. Kahn appointed University lecturer in economics and politics, A. H. Wilson, W. V. D. Hodge and P. Hall University lecturers in mathematics; gift by Mrs. G. Stephenson, 848; bequest by S. H. Bickham; Prof. D. B. Copland appointed Alfred Marshall lecturer for 1933–34; award of the Wyse studentship to Miss M. M. Hunter, 884; Dr. G. D. H. Bell appointed University demonstrator in agricultural biology; Dr. K. A. C. Elliott elected a fellow of Selwyn College, 920
Canada: National Research Council of: Report of the, for 1931–32, 869; Work of the, 648; Newfoundland, Bermuda, British West Indies, British Guiana and the Falkland Islands, Directory of Museums and Art Galleries in, Sir Henry A. Miers and S. F. Markham, 84; Radium in, Assays of, H. S. Spencer, 55; The Museums of, Sir Henry A. Miers and S. F. Markham, 84
Canadian: Minerals of the Rare Elements, H. V. Ellsworth, 660; Water Power Development in 1932, Dr. Brysson Cunningham, 788
Cancer: Hospital (Free) London, Research Grant for the; Appointment of Research Workers, 500, 509; -Producing Compounds, Sex Hormones and, Dr. J. W. Cook and Prof. E. C. Dodds, 205
Candles and Candle-Making, D. Allan, 269

Cannizzaro's Reaction, G. Lock (2), 560

Cantor : Georg, Gesammelte Abhandlungen : Mathematischen und Philosophischen Inhalts mit erläuternden Anmerkungen sowie mit Ergänzungen aus dem Briefwechsel Cantor-Dedekind, Herausgegeben von E. Zermelo (*Review*), 418 ; The Mathematician of the Infinite, Prof. H. T. H. Piaggio (*Review*), 418

Carbon : Dioxide in the Sea, 282 ; Fusion of, A. Egerton and M. Milford, 169 ; in the Diamond, Atomic Radius of, V. Posejpal, 410 ; Line $K\alpha$, Fine-Structure of the, M. Morand and A. Hautot, 143 ; Monoxide : Heats of Combustion of, in Oxygen, and of Nitrous Oxide in Carbon Monoxide at Constant Pressure, J. H. Awbery and Dr. E. Griffiths, 446 ; in Air, Detection of Traces of, Prof. H. Hartridge, 654 ; Dr. W. Ackermann, 441 ; H. R. Ambler and T. C. Sutton, 766

Carbonic Anhydrase and the State of Carbon Dioxide in Blood, late Dr. N. U. Meldrum and Dr. F. J. W. Roughton, 874

Carboniferous Molluscs of the Donetz Basin, D. M. Fedotov, 404

Carbonyls of Lithium, Rubidium and Cæsium, Dr. T. G. Pearson, 166

Carborundum Crystals, Photoconductive Effect in, Prof. Kamienski, 475

Caribou in Canada, Migration of, 373

Carnegie Institution, Central American Research by the, 809

Carnegie, The Last Cruise of the, Dr. J. H. Paul (*Review*), 114

Carotene Derivative, A, giving with Antimony Trichloride an Absorption Band at 610–630 mμ, M. van Eekelen and A. Emmerie, 275

Cartilage, Glycogen in, Dr. H. B. Fell and Dr. R. Robison, 62

Casein, New Researches on, E. Chorbuliez and F. Meyer, 215

Cassiopeiæ, γ, Spectrum of, Dr. W. J. S. Lockyer, 134

Catfish, Impulses from Sensory Nerves of, H. Hoagland, 631

Cathode Ray : Oscillography, R. A. Watson Watt, 66 ; Oscillograph, New Applications of the, 103 ; Photography of Random Electrical Transients, F. W. Chapman, 620 ; Tube, A Method of Extending the Frequency Range of the, Prof. H. Hartridge, 95

'Catkin' Radio Valve, The, 735

Cattle : Beef, Improvement of, in Australia, 576 ; Blood-Sucking Habit of a Bug, W. E. China, 806

Cave Paintings in the Pyrenees, N. Casterat, 19

Cavia, Early Stages in the Development of, N. H. W. Maclaren and Prof. T. H. Bryce, 922

Cellulose : Acetate : its Manufacture and Applications, A. G. Lipscomb (*Review*), 454 ; Products, Lignin Content of, Dr. A. G. Norman and S. H. Jenkins, 729 ; Structure of : Prof. H. Mark, 591 ; Prof. M. J. Duclaux, 553

Cenco News Chats, 200

Central-Asian Tracks : On Ancient, Brief Narrative of Three Expeditions in Innermost Asia and North-Western China, Sir Aurel Stein (*Review*), 415

Cephalic Index, Influence of the Variation of the, on that of the Alveolo-Palatinal and Superior Facial Indices, A. Perier, 815

Cepheid, The Respective Phases of Ionisation Maxima and Light Maxima in a, G. Tiercy, 483

Cepheids : Respective Phases of Minimum Ionisation and Light Minimum in the, G. Tiercy, 815 ; Variation of Ionisation and the Spectrum Variation of Some, G. Tiercy, 215

Cerebral Cortex, Functions of the Olfactory Parts of the, C. J. Herrick, 739

Cerebro-Spinal Meningitis, 128

Cetacea, Worms Parasitic in, Dr. H. A. Baylis, 551

Ceylon, Marine Biology in, Dr. J. Pearson, 54

Chain : Reactions, Reaction Cells in, A. R. Ubbelohde, 328 ; The Electromotive Force of the, Mlle. Quintin, 482

Charles and Erasmus, Dr. MacGregor Skene, 66

Chemical : Analysis : by the Emission Spectrum, Foundations and Methods of, Dr. W. Gerlach and Dr. E. Schweitzer (translated) (*Review*), 420 ; by X-Rays and its Applications, Prof. G. von Hevesy (*Review*), 39 ; Quantitative, Modern Methods in, Dr. A. D. Mitchell and Dr. A. M. Ward (*Review*), 531 ; Disarmament, 413 ; Engineers, Institution of, election of officers ; award of the Osborne Reynolds medal to S. G. M. Ure, the Moulton medal to Dr. C. M. White, and the Junior Moulton medal and prize to Dr. W. B. Hawes, 510 ; Incendiary and Bacterial Weapons Special Committee, Report of, 413 ; Industry : Petroleum Technology and, 145 ; Society of : Dr. J. T. Dunn elected president of the, 432 ; Prof. W. A. Bone awarded the medal of the, 793 ; *Physics, Journal of*, No. 1, 271 ; Society, Present Position and Future of the, Prof. G. G. Henderson, 498 ; Subjects, The Elder Pliny's Chapters on, Part 2. Edited, with translation and notes, by Dr. K. C. Bailey (*Review*), 305

Chemistry : and our Idiosyncrasies, Dr. E. F. Armstrong (*Review*), 314 ; and the Art of Living, Prof. H. E. Armstrong (Sir Jesse Boot Foundation Lecture), 795 ; Applied, Reports of the Progress of, Vol. 17, 1932 (*Review*), 786 ; Federal Council for, 300 ; Forensic and Scientific Criminal Investigation, A. Lucas. Second edition (*Review*), 115 ; Inorganic and Theoretical, A Comprehensive Treatise on, Dr. J. W. Mellor. Vol. 12 (Part 1), (*Review*), 638 ; in Space, Modern Aspects of, Prof. T. M. Lowry (*Review*), 563 ; Institute of, Address by Dr. G. C. Clayton ; presentation of the Meldola medal to Dr. L. E. Sutton, and the Sir Edward Frankland medal and prize to L. Young, 357 ; of the Higher Fungi, L. Lukacs and J. Zellner (22), 888 ; of the Lichens, J. Klima (2), 888 : Organic : An Introduction to, Prof. I. D. Garard (*Review*), 420 ; A Text-Book of, Prof. J. Schmidt. English edition by Dr. H. G. Rule. Second edition (*Review*), 116 ; Laboratory Methods of, L. Gattermann. Revised by H. Wieland. Translated by Dr. W. McCartney (*Review*), 78 ; Practical (*Review*), 78 ; Physical, Prof. J. Eggert. Translated by Dr. S. J. Gregg (*Review*), 419 ; A Text-Book of, Dr. J. Newton Friend. Vol. 1 (*Review*), 417 ; International Congress of, 53 ; Plant, Comparative, E. Fraenkel and J. Zellner (24), 888 ; Progress of, vol. 29, for 1932, Annual Reports on the (*Review*), 676 ; Raman Spectra and, 263 ; Space, Growth of, Prof. J. Read (*Review*), 783 ; Tannin, Incunabula of, Dr. M. Nierenstein (*Review*), 823 ; The A.B.C. of, J. G. Crowther (*Review*), 895

Chick Embryo, Induction by Coagulated Organisers in the, C. H. Waddington, 275

Chile Saltpetre, Origin of the, Dr. C. T. Kautter, 556

Chilean Insect Parasites for New Zealand, Dr. D. Miller, 283

Chimie, anorganischen, Handbuch der, Herausgegeben von Prof. R. Abegg, Dr. F. Auerbach und Prof. I. Koppel. Band 4, Abt. 3, Teil 2B, Lief. 2 (*Review*), 491

Chimney : Emissions, Reduction of, 234 ; Smoke, Measurement of, 430

China, Ancient : Copper Age in, Tsurumatsu Dono, 243 ; 917 ; Festivals and Songs of, Prof. M. Granet. Translated by Dr. E. D. Edwards (*Review*), 346 ; and American Scientific Expeditions, Dr. H. F. Osborn, 87 ; An Imperial City of (*Review*), 184 ; Land and Labour in, Prof. R. H. Tawney (*Review*), 712

Chinese : Chemical Society, Journal of the, No. 1,907 ; Medicine : History of, being a Chronicle of Medical Happenings in China from Ancient Times to the Present Period, Dr. K. Chimin Wong and Dr. Wu Lien-Teh (*Review*), 527

Chitons, Abnormal, I. Taki, 367

Chlorine : Hydrogen and, Photochemical Reaction of : Prof. H. B. Baker, 27 ; Prof. A. J. Allmand, 656 ; Magnetic Rotatory Power of, and of Hydrochloric Acid Gas, R. de Mallemann and P. Gabiano, 286

Chlorophyll, Attenuation of the, shown by Parasitic Green Plants, M. Molliard, 178
Chlorophylls, Structural Formulæ of the, Prof. J. B. Conant and Emma M. Dietz, 131
Cholera Vibrion, Transmissible Lysis of the, P. N. Bernard and J. Guillerm, 887
Cholesterol: Chemical Constitution of, and a New Isomeride of Cholesterol, R. de Fazi, 924; of the Human Brain, C. Antoniani and F. Zanelli, 71
Christening, Caution in, Prof. H. E. Armstrong, 330
Christian Church: Phases of the, a Short View of its History, Rev. A. C. Bouquet (*Review*), 677
Chromic Salts, Line Absorption of, in Relation to Co-ordination, Dr. C. H. Johnson and A. Mead, 399
Chromosome: Mechanics, Prof. A. H. Sturtevant (*Review*), 5; Numbers in Vertebrates, K. Oguma and S. Kakino, 403
Chromosomes and Plant-Breeding, Dr. C. D. Darlington (*Review*), 5
Chronophotographic Method, A Modification of the, and Some Applications, E. Crausse and J. Baubiac, 482
Chrysene: Substituted βγ-Diphenyladipic Acids and Derivations of, Dr. A. I. Vogel, 402; Synthesis of, and Certain Derivatives, G. R. Ramage and Prof. R. Robinson, 205
Cinematography, New Lens of High Rapidity for, Carl Zeiss, 475
Circuit-Breakers, Heavy Current, H. Thommen, 103
Circular Magnetic Dichroism and Magnetic Rotatory Dispersion, A. Cotton, 70
Citrus, Mycorrhiza in the Genus, Dr. M. C. Rayner, 399
Civilisation and War (*Review*), 635
Clarendon Laboratory, Oxford, Helium Liquefaction Plant at the, Prof. F. A. Lindemann and T. C. Keeley, 191
Climate: a Handbook for Business Men, Students and Travellers, Dr. C. E. P. Brooks. Second edition (*Review*), 9; and Acclimatization: Some Notes and Observations, Sir Aldo Castellani (*Review*), 712
Climatic Temperature, Minimum, C. F. Talman, 431
Clinical Laboratory Methods, A Manual of, Dr. C. L. Cummer. Third edition (*Review*), 116
Clothes Moths and House Moths, Major E. E. Austen, assisted by A. W. McKenny Hughes, 55
Cloud Photography, International, 577
Clover Mites invade Dwelling-Houses, 557
Coal: Economic Significance of, Capt. B. Acworth, 478; for Sea Transport, Rear-Admiral Scott-Hill, 479; Formation of Rock Joints and the Cleat of, Profs. P. F. Kendall and H. Briggs, 922; Industry, British: Early History of the (*Review*), 311; The Rise of the, Prof. J. U. Nef. 2 vols. (*Review*), 311; Low Temperature Carbonisation of, 31; -Mining Explosives, Recent Developments in, Dr. W. Payman, 846; The Utilisation of: 633; A. C. Hardy, and others, Symposium on the, 478
Cobalt: Chloride: Constitution of Hydrochloric Acid Solutions of, P. Job, 338; Solutions of, Circular Magnetic Dichroism and Abnormal Magnetic Rotatory Dispersion of, M. Scherer, 70; Ion of Dissolved, Paramagnetism of the, R. Mercier, 338
Cæsium Vapour, Absorption of Light in, Dr. H. J. J. Braddick and Prof. R. W. Ditchburn, 132
Coffee, Root Development in, Distribution of Nitrates in the Soil and, V. A. Beckley and F. McNaughtan, 878
Col du Marchairuz Region, The Virgulian and the Stratigraphy of the Portlandian of the, A. Lombard, 815
Colloidal: Propellants, Rate of Burning of, Dr. A. D. Crow and W. E. Grimshaw, 60; F. R. W. Hunt and G. H. Hinds, 206; Solutions, Surface Tension of, and the Action of Light on Soap Solutions, Dr. P. Lecomte du Noüy, 689
Colloids: Adsorption of, by Metallic Surfaces and its Influence on the Adherence of Electrolytic Deposits, P. Jacquet, 702; Flocculation of, Influence of Radioactive Radiations on the, A. Boutaric and Mlle. Madeleine Roy, 738; Preparation of, by Ultrasonic Dispersion, N. Marinesco, 410
Colonial: Educational Conference, Case for a, Sir George Maxwell, 812; Office Appointments, 55; 871
Colonisation of a Disused Millpond at Hillsborough, Co. Down, Common and Cairns, 702
Colorado, University of, Studies, Nov., 885
Coloration Problems in Animals, 577
Colour, A Simple Method for Determining, E. Haschek and M. Haitinger, 411
Comba Region, Geology of the, H. Lagotala, 411
Comenius in England: the Visit of Jan Amos Komenský (Comenius), the Czech Philosopher and Educationist, to London in 1641–1642; its Bearing on the Origins of the Royal Society, on the Development of the Encyclopædia, and on Plans for the Higher Education of the Indians of New England and Virginia, as described in Contemporary Documents. Selected, translated and edited, with an Introduction and Tables of Dates, by R. Fitzgibbon Young (*Review*), 306
Comet: Halley's, in 1909–11, Dr. A. C. D. Crommelin, 282; New, 1933*a*., 281; Peltier-Whipple, 173; Pons-Winnecke, Periodic, 697
Comets: 661; 845; Prof. van Biesbroeck, 245; of A.D. 868 and 1366, Dr. S. Kanda, 31; Perturbations of, by the Stars, E. Opik, 209
Comital Flora of the British Isles (Flora Comitalis Britannicæ: Fl. Com. Brit.): The, being the Distribution of British (including a number of Non-Indigenous) Plants throughout the 152 Vice-Counties of Great Britain, Ireland and the Channel Islands, with the Place of Growth, Elevation, World-Distribution, Grade, Chief Synonyms and First Names by which the Plants were recorded as British. By Dr. G. Claridge Druce. With an original coloured Map showing the Botanical Vice-Counties presented by W. J. Patey (*Review*), 309
Commonwealth Fund fellowships, awards of, 736
Compensating Plate Currents, Method of, P. Donzelot and J. Divoux, 106
Composite Surfaces in Higher Space, J. G. Semple, 886
Compressed Air Wind Tunnel at the National Physical Laboratory, New, 442
Cone, Motion of a, at High Speeds in Air, Taylor and Maccoll, 552
Consolidated Gold Fields of South Africa, Ltd., awards of the, 432
Constants and Numerical Data, Annual Tables of, Vol. 8, 2 parts; Vol. 9; Tables des matières du Vol. 9 (*Review*), 892
Convention and Fact, Dr. N. R. Campbell, 237
Co-operative Industrial Research, 817
Copepods: of the Woods Hole Region, Mass., The, Dr. C. B. Wilson, 698; Sexual Reproduction in, A. G. Lowndes, 240
Copper: -Aluminium Alloys, X-Ray Investigation of the, A. J. Bradley and Phyllis Jones, 589; Properties of, Influence of Oxygen on the, W. Broniewski and S. Jasian, 338
Corallian Rocks of Yorkshire, V. Wilson (1), 595
Corals, Growth of, T. Tamura and Y. Hada, 172

CORRESPONDENCE

Acetic Acid: at 25°, Dissociation Constant of, Limiting Mobilities of Some Monovalent Ions and the, Dr. A. I. Vogel and G. H. Jeffery, 27; in Water, Dissociation of, Dr. C. W. Davies and W. H. Banks, 328
Acetylated Aldonic Nitriles, A Rule for the Rotatory Direction of the, Dr. V. Deulofeu, 548
Acquired Characters, Inheritance of, Dr. R. L. Jenkins, 95
Adenine: Hydrochloride, Crystal Structure of Vitamin B_1, and of, J. D. Bernal and D. Crowfoot, 911; Vitamin B_4 and, R. D. Heard, H. W. Kinnersley, J. R. O'Brien, Prof. R. A. Peters and V. Reader, 617
Adrenal Gland, Vitamin C in the, G. Bourne, 874
Animal Life, Components of the Atmosphere and Synthetic Gases in Relation to, Prof. J. W. Hershey, 238

Alkali Metals, Remarkable Optical Properties of the, Prof. R. W. Wood, 582
Alkyl Groups, Volumes of, and their Orienting Powers, Dr. R. J. W. Le Fèvre, 655
Alkylanilines with Tertiary Alkyl Groups, Dr. W. J. Hickinbottom, 762
Allium, Somatic Chromosomes in, Structure and Division of, Prof. T. K. Koshy, 362
Aluminium: Hydride, Band Spectrum of, Predissociation and Pressure Effects in the, Prof. E. Hulthén and R. Rydberg, 470; Hyperfine Structure in, R. Ritschl, 58; Single Crystals, Recrystallisation Power and Shear Hardening in, Dr. W. G. Burgers, 326
Angiosperms, Origin of, Prof. G. R. Wieland, 360
Animal Growth, Heterogony and the Chemical Ground-Plan of, C. H. Waddington, 134
Anode Spot in a Neon Tube, Dr. T. Takamine, T. Suga and A. Yanagihara, 584
Antimony, Molecular Fluorescence of, Jean Genard, 132
Aphanapteryx, The Dodo and the, G. Renshaw, 728
Aquatic Insect Larvæ, Tracheal and Blood Gills in, Dr. W. H. Thorpe, 549
Arsenic, Nuclear Moment of, M. F. Crawford and A. M. Crooker, 655
Ascaphus, The 'Tail' of the Male American Toad, Prof. C. G. S. de Villiers, 692
Ascorbic Acid: Prof. A. Szent-Györgyi and Prof. W. N. Haworth, 24; Constitution of, Dr. E. L. Hirst, E. G. V. Percival and F. Smith, 617; Vitamin C and, A. L. Bacharach, 364; (Vitamin C) and Glutathione in Animal Tissues, Estimation and Distribution of, T. W. Birch and Dr. W. J. Dann, 469
Astronomical Radiative Stability, The, Sir Joseph Larmor, 805; Dr. G. C. Simpson, 875
Atmosphere, Components of the, and Synthetic Gases in Relation to Animal Life, Prof. J. W. Hershey, 238
Atomic Number Zero, The Neutron and Neuton, the New Element of, Prof. W. D. Harkins, 23
Bacterial Growth Curve, The, and the History of Species, Dr. A. S. Corbet, 61
Baltic, Inertia Currents in the, T. Gustafson and B. Kullenberg, 586
Band Spectra which appear near Visible Triplet Lines of Mercury, E. Matuyama, 58
Barium: Azide, Acceleration of the Decomposition of Crystals of, by the Emission from Radium Emanation, Prof. W. E. Garner and C. H. Moon, 513; Oxide (BaO), Band Spectrum of, P. C. Mahanti, 402
Barley, Egyptian Neolithic, A. Jackson, 652
p-Benzoquinone Crystal, Orientations of Molecules in the, K. S. Krishnan and S. Banerjee, 653
Beryllium and Helium, Lord Rayleigh, 724
Binary Alloys at Room Temperature, Constitution of, Prof. A. N. Campbell, 438
Biology, Teaching of, W. B. Yapp, 203
Blood Pigments of the Invertebrates, Molecular Weights of the, Prof. The Svedberg and Astrid Hedenius, 325
Boric Acid in Sea Water and its Effect on the Carbon Dioxide Equilibrium, K. Buch, 688
Borrowed Days, The, Sir Herbert Maxwell, Bt., 515
British Solomon Islands, Early History of the, R. J. A. W. Lever, 587
Bromine: Spectra of, Br V, VII and IV, A. S. Rao and Dr. K. R. Rao, 170
B. salmonicida in River Waters, The Presence of a Bacteriophage for, Dr. C. Todd, 360
'Bull-Dog' Calf in African Cattle, J. Carmichael, 878
Cadmium Hydride, Isotope Effect in the Spectrum of, E. Svensson, 28
Cæsium Vapour, Absorption of Light in, Dr. H. J. J. Braddick and Prof. R. W. Ditchburn, 132
Calcite, Solarisation of, Periodicity in the, S. Iimori, 619
Calcium Isotope with Mass 41 and the Radioactive Half-Period of Potassium, Prof. J. Kendall, W. T. Smith and T. Tait, 688
Cancer-Producing Compounds, Sex Hormones and, Dr. J. W. Cook and Prof. E. C. Dodds, 205
Carbon: Fusion of, A. Egerton and M. Milford, 169; Monoxide in Air, Detection of Traces of, Prof. H. Hartridge, 654; H. R. Ambler and T. C. Sutton, 766
Carbonic Anhydrase and the State of Carbon Dioxide in Blood, late Dr. N. U. Meldrum and Dr. F. J. W. Roughton, 874
Carbonyls of Lithium, Rubidium and Cæsium, Dr. T. G. Pearson, 166
Carotene Derivative giving with Antimony Trichloride an Absorption Band at 610–630 mμ, A. M. van Eekelen and A. Emmerie, 275
Cartilage, Glycogen in, Dr. H. B. Fell and Dr. R. Robison, 62
Cassiopeiæ, γ, Spectrum of, Dr. W. J. S. Lockyer, 134
Cathode Ray: Photography of Random Electrical Transients, F. W. Chapman, 620; Tube, Frequency Range of the, A Method of Extending the, Prof. H. Hartridge, 95
Cellulose Products, Lignin Content of, Dr. A. G. Norman and S. H. Jenkins, 729
Chain Reactions, Reaction Cells in, A. R. Ubbelohde, 328
Chick Embryo, Induction by Coagulated Organisers in the, C. H. Waddington, 275
Chlorine, Hydrogen and, Photochemical Reaction of, Prof. H. B. Baker, 27; Prof. A. J. Allmand, 656
Chlorophylls, Structural Formulæ of the, Prof. J. B. Conant and Emma M. Dietz, 131
Christening, Caution in, Prof. H. E. Armstrong, 330
Chromic Salts, Line Absorption of, in Relation to Co-ordination, Dr. C. H. Johnson and A. Mead, 399
Chrysene: and Certain Derivatives, Synthesis of, G. R. Ramage and Prof. R. Robinson, 205; Substituted βγ-Diphenyladipic Acids and Derivatives of, Dr. A. I. Vogel, 402
Citrus, Mycorrhiza in the Genus, Dr. M. C. Rayner, 399
Coffee, Root Development in, Distribution of Nitrates in the Soil and, V. A. Beckley and F. McNaughtan, 878
Colloidal: Propellants, Rate of burning of, Dr. A. D. Crow and W. E. Grimshaw, 60; F. R. W. Hunt and G. H. Hinds, 206; Solutions, Surface Tension of, and the Action of Light on Soap Solutions, Dr. P. Lecomte du Noüy, 689
Convention and Fact, Dr. N. R. Campbell, 237
Copepods, Sexual Reproduction in, A. G. Lowndes, 240
Cosmic: Radiation, Origin of, H. Alfvén, 620; Rays, Energy of, Prof. E. Regener, 130
Crustacea, Respiratory Movements in, Control of, Prof. H. Munro Fox and M. L. Johnson, 514
Crystal: Lattice Constants, Determination of, by Electron Diffraction, Prof. G. I. Finch and A. G. Quarrell, 842; Structure and Orientation in Thin Films, Prof. G. I. Finch and A. G. Quarrell, 877
Crystalline Style, Oxidase of the, C. Berkeley, 94
Cuprous Oxide: A New Type of Photoelectric Effect in, in a Magnetic Field, Dr. I. Kikoin and Dr. M. Noskov, 725; Photo-Cell in Red Light, Reversal of the Current from a, Dr. H. H. Poole and Dr. W. R. G. Atkins, 133
Curare, The Neuro-Muscular Junction and, Tudor Jones, 693
Davainea proglottina, Life-History of the Fowl Tapeworm, F. J. Brown, 276
Debye's Dispersion of Nitrobenzene, Prof. J. Weigle and R. Luthi, 327
Dehydro-Ascorbic Acid, Constitution of, Prof. P. Karrer, H. Salomon and K. Schöpp, 800
Diphenyl Series, Crystal Structure of, Lucy W. Pickett, 513
Dodo, The, and the Aphanapteryx, G. Renshaw, 728
Dyes, Anti-Stokes Fluorescence in, Efficiency of, Dr. A. Jabłoński, 839
Earthquakes: in the Holy Land: a Correction, Prof. Bailey Willis, 550; *P* Wave in, Corrections to the times of the, Dr. H. Jeffreys and K. E. Bullen, 97
Egyptian Neolithic Barley, A. Jackson, 652
Einstein", "The Case Against, Col. A. Lynch, 622
Elastic Electron Scattering in Gases, Dr. S. Werner, 726
Electrical Energy by Frog-Skin, Output of, W. L. Francis, 805

Electrolytic Dissociation, Rôle of the Solvent in, Dr. A. R. Martin, 584; Dr. J. A. V. Butler and Miss L. C. Connell, 800

Electrometer Triode in the X-Ray Ionisation Spectrometer, Dr. W. A. Wooster, 545; Dr. B. W. Robinson, 546

Electron: Diffraction: by Films of Grease, Prof. G. P. Thomson and C. A. Murison, 237; by Vapours, Dr. H. de Laszlo, 803; Polarisation ?, Prof. R. Whiddington, 908; Positive, A Possible Property of the, Dr. W. Elsasser, 764

Electronic Oscillations, Production of, with a Two-Electrode Valve, J. S. McPetrie, 691

Electrons in Amorphous and in Crystalline Antimony, Diffraction of, J. A. Prins, 760

Elements: Artificial Transmutation of, Chemical Detection of, Prof. F. A. Paneth and P. L. Günther, 653; Light, Disintegration of, by Fast Protons, Dr. J. D. Cockcroft and Dr. E. T. S. Walton, 23

Ergosterol and Cholesterol, Hydroxyl Group in, Prof. I. M. Heilbron and J. C. E. Simpson, 438

'Events', 'Time' and, Ideas of, W. W. L., 727

Explosive Chain: Reaction between Hydrogen and Oxygen, Upper Pressure Limit in the, C. N. Hinshelwood and G. H. Grant, 361; Reactions, Upper Limit in, H. W. Melville and H. L. Roxburgh, 690

Fact, Convention and, Dr. N. R. Campbell, 237

Ferns, Sporangia containing Spermatozoids in, Alice E. Gairdner, 621

Ferromagnetics, Atomic Moments of, Dr. E. C. Stoner, 433

Fibres from the Coat of a Blackface Lamb, Dr. S. G. Barker, 799

Fluorescence, Negative Polarisation in, K. S. Krishnan and S. M. Mitra, 204

Fluorite from Obira, Japan, Thermoluminescence Spectrum of, Bands in the, Ei-ichi Iwase, 909

Formaldehyde in Dew, Presence of, Prof. N. R. Dhar and Atma Ram, 800

Fossil Bones, Preservation of, L. McL. Mann, 366; W. J. McCallien, 694

Fourier Analysis and Vowel Curves, R. H. Nisbet, 401

Frog, Hermaphrodite, A, A. M. Gardiner, 330

Frogs, Spawning in, Factors Controlling Date of, R. M. Savage, 587

Fuel-Knock, A Theory of, Dr. S. Steele, 724

G., The Constant of Gravitation, Prof. V. V. Narlikar, 134

Gallium Isotopes 69 and 71, Nuclear Moments of the, J. S. Campbell, 204

Gammarus chevreuxi, Sexton, Further Mutations in the Amphipod, Mrs. E. W. Sexton and Miss A. R. Clark, 201

Gases, Mixtures of, Conductivity of, Dr. S. P. McCallum and L. Klatzow, 841

Glucose Metabolism, Glutathione, Iodoacetic Acid and, Dr. J. H. Quastel, 206

Glucuronic Acid, A New Unsaturated Derivative of, J. Pryde and R. T. Williams, 57

Glutathione: and Tissue Glyoxalase, Iodoacetic Acid, Dr. F. Dickens, 130; Iodoacetic Acid and Glucose Metabolism, Dr. J. H. Quastel, 206

Glycogen in Cartilage, Dr. H. B. Fell and Dr. R. Robison, 62

Glycuronic Acid, Methylnornarcotine, and Vitamin C, W. J. Dann, 24

Glyoxalase, Tissue, Iodoacetic Acid, Glutathione and, Dr. F. Dickens, 130

Gold, Organic Compounds of, Prof. C. S. Gibson, 130

Gonad-Stimulating Hormones in Hypophysectomised Animals, Prof. J. B. Collip, Dr. H. Selye and Prof. D. L. Thomson, 56

Graticules, Photographic, Sir Herbert Jackson, 766

Heart, Abnormal Movability of the, S. Osawa, 241

Helium, Beryllium and, Lord Rayleigh, 724

Helminthosporium avenæ, Sporulation of, in Artificial Culture, W. A. R. Dillon Weston, 435

'Hexuronic Acid' (Ascorbic Acid) as the Antiscorbutic Factor, Prof. A. Szent-Györgyi and Prof. W. N. Haworth, 24; T. W. Birch, Dr. L. J. Harris, S. N. Ray, 273; W. J. Dann, 274

Hibernian Halos, Radioactivity of Samarium and the Formation of, Dr. J. H. J. Poole, 654

High-Frequency Electric Discharge in Gases, J. C. Wilson, 546

Hydrocarbon Combustion in an Engine, A. Egerton and F. Ll. Smith, 725

Hydrogen and Chlorine, Photochemical Reaction of, Prof. H. B. Baker, 27; Prof. A. J. Allmand, 656

Hydroxyl Group: in Ergosterol and Cholesterol, Prof. I. M. Heilbron and J. C. E. Simpson, 438; The, and Soap Film Structure, W. J. Green, 873

Hygroscopy, Capacitance, and Some of its Applications, Dr. R. K. Schofield, 96; Dr. W. L. Balls, 329

Immiscible Liquid Layers, Four, Systems of, E. Lester Smith, 167

Impulse Generator, A New, for Three Million Volts, T. E. Allibone, F. S. Edwards and D. B. McKenzie, 129

Insects: and Micro-Climates, H. S. Leeson and K. Mellanby, 363; Dr. H. H. Darby, 837; Inhabiting the Soil Surface, Effects of Rainfall-Evaporation Ratio on, Dr. J. Davidson, 837

Intelligence in Man, Inheritance of, A. F. Dufton, 763; Dr. C. C. Hurst, 764

Internal Ballistics, The Combustion Problem of, Dr. A. D. Crow and W. E. Grimshaw, 805

Invar, Dr. Ch.-Ed. Guillaume, 658

Iodine: Arc Spectrum of, Prof. W. E. Curtis, 398; -Oxalate Reaction, Kinetics of the, Prof. N. R. Dhar, A. K. Bhattacharya and B. L. Mukerji, 840; Vapour at High Temperatures, Absorption Bands of, E. Skorko, 366

Iodoacetic Acid: and Glucose Metabolism Glutathione, Dr. J. H. Quastel, 206; Glutathione and Tissue Glyoxalase, Dr. F. Dickens, 130

Ionisation Produced by Radioactive Sources, Amplification of the, J. A. C. Teegan, 277

Ionosphere: Characteristics of the, J. P. Schafer and W. M. Goodall, 804; Fine-Structure of the, Prof. E. V. Appleton, 872; J. A. Ratcliffe and E. L. C. White, 873

Ions, Monovalent, Limiting Mobilities of Some, and the Dissociation Constant of Acetic Acid at 25°, Dr. A. I. Vogel and G. H. Jeffery, 27

Kattegat, Boundary Tides in the, Dr. H. Pettersson and B. Kullenberg, 586

Kennelly-Heaviside Layer, Polarisation of Echoes from the, T. L. Eckersley, 512

Latitude, Variation Effect in, Correlatable with the Moon, Prof. H. T. Stetson, 437

Lattice Distortion, Selective, in Wires under Torsion, W. A. Wood, 842

Lepidosiren, Pelvic Filaments of, J. T. Cunningham and D. M. Reid; G. E. H. Foxon, 913

Liesegang Rings, Dr. E. S. Hedges, 169

Lightning Flash, A Destructive, Dr. C. V. Boys, 765

Light: Measurement of, for Biological Purposes, Dr. W. H. Pearsall and P. Ullyott, 694; -Spots, Faint Transient, Photography of, Dr. L. F. Richardson, 401

Liquids, Supersaturation of, with Gases, T. N. Richardson and Dr. K. C. Bailey, 762

Local Lists of Animals, Prof. A. E. Boycott, 94

Lolium: Nitrogen Fixation in the Genus, R. Brown, 169; Seedlings, Fluorescence of, in Ultra-Violet Light, P. A. Linehan and Prof. S. P. Mercer, 202

Loudness, Scales of, B. G. Churcher and A. J. King, 760

Lunar Periodicity in Reproduction, Prof. T. A. Stephenson, 622

Magnetic Disturbances, Recent, Rev. J. P. Rowland, 764

Mars, The Minor Details of the Planet, Dr. E. M. Antoniadi, 802

Mayas, Sacred Sandstone of the, Prof. T. D. A. Cockerell, 656

Mendelian Factors in Quantitative Inheritance, Number of, Dr. R. A. Fisher, 400

Methionine in Wool, J. Barritt, 689

Methylnornarcotine, Glycuronic Acid, and Vitamin C, W. J. Dann, 24

Mice under Continued Treatment with Œstrin, Some Effects Observed in, H. Burrows, Prof. E. C. Dodds, and N. M. Kennaway, 801

Mitochondria, Fixation of, J. H. Davie, 59

Molecules of Intermediate Complexity, Kinetics of the Decomposition of, C. N. Hinshelwood and C. J. M. Fletcher, 24

Molybdenum, Distribution of, Dr. W. A. Roach, 202

Mussel, Common, Strange Spatfall of the, on the Common Cockle, Prof. J. H. Orton, 513

Mutations, Spontaneous, Origin of, M. Navashin, 436

Neoteny and Pædogenesis, Meaning of, G. E. H. Foxon, 93

Neuro-Muscular Junction, The, and Curare, Tudor Jones, 693

Neuton, The Neutron and, the New Element of Atomic Number Zero, Prof. W. D. Harkins, 23

Neutron: and Neuton, The, the New Element of Atomic Number Zero, Prof. W. D. Harkins, 23; Proton and Positron, Dr. N. Thon, 878

Neutrons, Dr. D. Meksyn, 366

Nerve: Action of Quaternary Ammonium Salts on, S. L. Cowan, 658; Mitogenetic Radiation of, Dr. A. Gurwitsch, 912

Nitrates in the Soil, Distribution of, and Root Development in Coffee, V. A. Beckley and F. McNaughtan, 878

Nitrobenzene, Debye's Dispersion of, Prof. J. Weigle and R. Luthi, 327

Nitrogen Dioxide: Infra-Red Absorption Spectrum of, C. R. Bailey and A. B. D. Cassie, 239; Molecule, Form and Vibrational Frequencies of the, C. R. Bailey and A. B. D. Cassie, 910; R. Schaffert, 911

Nitrous Oxide in the Glow Discharge, Dissociation of, E. A. Stewardson, 364

NO_2: Extension of the Visible Absorption System of, to Longer Wave-Lengths, J. Curry and Dr. G. Hertzberg, 842; Molecule, Form and Vibrational Frequencies of the, Dr. L. Harris, W. S. Benedict and G. W. King, 621

Nematodes, Parasitic, Cultivation of, G. Lapage, 583

Nuclear: α-Particles, Fundamental State of, Dr. G. Gamow, 618; Energy Levels, Dr. G. Gamow, 433; Potential Barriers: and Nuclear Structure, Heights of, E. C. Pollard, 398; Heights of, E. C. Pollard, 97

Nucleic Acids and Uracil, Irradiation of, F. F. Heyroth and J. R. Loofbourow, 92

Numerical Coincidence, A, H. P. Hollis, 550

Oestrogenic Substance from Plant Material, An, Dr. B. Skarżyński, 766

Oestrus-Exciting Compound, A Synthetic, Dr. J. W. Cook, Prof. E. C. Dodds and C. L. Hewett, 56

Oldoway Human Skeleton, The, Dr. L. S. B. Leakey, Prof. H. Reck, Prof. P. G. H. Boswell, A. T. Hopwood and Dr. J. D. Solomon, 397

Olefinic Compounds, Catalytic Hydrogenation of, Dr. E. H. Farmer and R. A. E. Galley, 60

Orthopodomyia pulchripalpis, Rondani (Diptera, Culicidæ), A New British Record of, J. F. Marshall and J. Staley, 435

Ovulation without 'Heat' in the Ewe, Occurrence of, R. Grant, 802

Oxide Catalysts, Positive Ion Emission from, Dr. C. F. Powell and Luang Brata, 168

Oysters (O. *edulis*), Breeding of, at Port Erin, Prof. J. H. Orton, Miss M. W. Parke and W. C. Smith, 26

Ozone, Photosensitised Decomposition of, by Chlorine, Dr. R. G. W. Norrish and G. H. J. Neville, 544

P. vulgata, Environment of the Common Limpet, Some Limiting Factors in the, Prof. J. H. Orton, 693

Pædogenesis, Neoteny and, Meaning of, G. E. H. Foxon, 93

Paramagnetic Susceptibility, Influence of Light on, P. W. Selwood, 761

Pelagic Organisms, Unusual Occurrence of, Prof. W. J. Dakin, 239; G. P. Farran, 240

Penetrating Radiation, Spectrum and Latitude Variation of, Dr. E. J. Williams, 511

Phenomenal Regression to the Real Object, Prof. W. Peddie; Dr. R. H. Thouless, 544

Phosphorus, Oxide of, Ultra-Violet Bands of, Prof. P. N. Ghosh and A. K. Sen Gupta, 841

12-Phosphotungstic Acid, Structure of the Molecule of, J. F. Keggin, 908

Phytophthora megasperma causing Pink Rot of the Potato, H. Cairns and A. E. Muskett, 277

Piltdown Skull, The Second, Sir Arthur Smith Woodward, 242

Pituitary Gland, Action of Proteolytic Enzymes on the Oxytocic Principle of the, Dr. J. M. Gulland and T. F. Macrae, 470

Plant Virus, Protective Inoculation against a, Dr. R. N. Salaman, 468

Plasticine Edible? Is, D. I. Clements, N. H. Howes and G. P. Wells, 330

Positive Electron, New Evidence for the, Dr. J. Chadwick, P. M. S. Blackett and G. Occhialini, 473

Positron, Neutron, Proton, and, Dr. N. Thon, 878

Potassium, Radioactive Half-Period of, Calcium Isotope with Mass 41 and the, Prof. J. Kendall, W. T. Smith and T. Tait, 688

Potatoes, Virus *A* of, Insect Transmission of, J. B. Loughnane, 838

Priestley: as a Practical Chemist, Prof. T. S. Patterson 690; Dr. A. N. Meldrum, 801; Joseph, The "Leeds Portrait" of, W. C. Walker, 876

Protein, Synthesis of, by Green Plants, L. Loose and Dr. W. H. Pearson, 362

Proton, Neutron, Positron, Dr. N. Thon, 878

Puccinia Helianthi Schw., Union of Pycniospores and Haploid Hyphæ in, J. H. Craigie, 25

Pycnogonid, A Dodecapodous, Dr. W. T. Calman, 242

Pyrrhotite, Iron Lattice of, Vacant Positions in the, Prof. G. Hägg, 167

Radio-Waves? Interaction between, B. D. H. Tellegen, 840

Rare Earths, Pure Salts of the, Fluorescence of, Prof. R. Tomaschek and O. Deutschbein, 473

'Raw' Weather, Prof. W. A. Osborne, 515

Rectifier Photo-Cells, Reversal of Current in, J. Guild, 327; Dr. H. H. Poole and Dr. W. R. G. Atkins, 547

Reproduction, Lunar Periodicity in, Prof. T. A. Stephenson, 622

Resonance Ag I Lines, Fine-Structure of the, W. E. Williams and A. Middleton, 692

Rickets, Experimental, as a Phosphorus Deficiency Disease, Prof. H. D. Kay and Dr. B. L. Guyatt, 468

Ringworm Fungi, Development of Fuseaux, Aleuriospores and Spirals on detached Hairs infected by, Dr. A. M. Davidson and Dr. P. H. Gregory, 836

Rubber Research, Dr. S. S. Pickles, 273

Sabellids, Blood Circulation in, Reversible Stoppage of the, Prof. H. Munro Fox, 26

Samarium: Radioactivity of, and the Formation of Hibernium Halos, Dr. J. H. J. Poole, 654: Range of Radiation from, Prof. G. Hevesy and Dr. M. Pahl, 434

Schneider Mediumship, Further Light on the, Lord Charles Hope, 549; H. Price, 658

Scientific Centralisation in the British Empire, Prof. C. Stanton Hicks, 397

Seismographs, Hydraulic, Prof. S. K. Banerji and K. N. Sohoni, 547

Sex: Artificial Control of, in the Progeny of Mammals, Prof. N. K. Koltzoff and V. N. Schröder, 329; Hormones and Cancer-Producing Compounds, Dr. J. W. Cook and Prof. E. C. Dodds, 205

Sheep, Nutritional Condition of, and Susceptibility to Stomach Worm, A. H. H. Fraser and Dr. D. Robertson, 94

Silver, Arc Spectrum of, Structure of the Lines of the, D. A. Jackson, 691

Snails and Changes in Sea-Level, Prof. T. D. A. Cockerell, 277

Soap Film Structure, The Hydroxyl Group and, W. J. Green, 873

Sodium Benzoate, Chlorination of, Dr. J. C. Smith, 28

Soot Films and Oil, Interaction between, J. H. Coste, 691; Dr. S. C. Blacktin, 873

Spearman's General Factor, Ambiguity in Sign of, Prof. H. T. H. Piaggio, 170

Species, History of, The Bacterial Growth Curve and the, Dr. A. S. Corbet, 61

Spectral Lines in Indium and Gallium, Relative Intensity of, Miss R. Payne-Scott, 365
Sponges, Light-Producing Powers of, Prof. E. Trojan, 728
'Stainless-Invar', A New Alloy, Prof. Kôtarô Honda, 587
Strepinema Stage in Reduction, Prof. H. H. Dixon, 437
Sulphur: Hexafluoride, K. G. Denbigh and Prof. R. Whytlaw-Gray, 763; -Hydrogen Reaction, New Experimental Evidence in the, E. E. Aynsley, Dr. T. G. Pearson and Dr. P. L. Robinson, 471
Sunspots on the Solar Disc, Zones of Apparent Inhibition of, Prof. J. A. Carroll, 548
Supersonic Vibrations set up in a Zinc Bar undergoing Transverse Vibrations, Prof. K. Prosad and S. Sharan, 803
Syllis ramosa, McIntosh, Distribution of the Polychæte Worm, Dr. C. Crossland, 242
Symmetrical Region, Variation Problems for a, Prof. H. Bateman; Prof. E. T. Whittaker, 472
Tektites, Origin of, F. Chapman; Dr. L. J. Spencer, 876
Tellurium Fluorescence, Magnetic Quenching of, R. Smoluchowski, 914
Thunderstorms, Summer, S. Morris Bower, 473
'Time': and 'Events', Ideas of, W. W. L., 727; Determination, Dr. J. de Graaff Hunter, 515; Measurements, Number 60 in, Prof. H. Chatley, 914
Timothy Grass, A Fly Post of, L. A. L. King and Agnes A. Meikle, 837
Trees, Twisted, H. G. Champion, 133
Triatomic Molecules, Structure of, A. B. D. Cassie, 438
Ultra-Sonic Radiation, Chemical and Biological Effects of, Prof. A. Szent-Györgyi, 278
Units, Fundamental, Dimensions of, Prof. H. Stansfield, 59; Prof. F. M. Denton, 585
Uracil, Nucleic Acids and, Irradiation of, F. F. Heyroth and J. R. Loofbourow, 92
Vibrating Metal Bars, Viscous Damping of, Prof. K. Sezawa, 803
Virus Diseases and Intracellular Inclusions in Plants, Dr. F. M. L. Sheffield, 325
Viscosity Measurements of Liquids by the Oscillating Disc Method, Prof. C. E. Fawsitt, 97
Visual Experience, A Peculiar, Dr. F. A. Bather, 62
Vitamin A: Absorption Spectrum of, at Low Temperatures, Dr. F. P. Bowden, S. D. D. Morris, and Dr. C. P. Snow, 582; Highly Active, Characteristics of, Dr. F. H. Carr and W. Jewell, 92; in Cod Liver Oil, An Inhibitor of the Antimony Trichloride Test for, A. Emmerie, 364; B_1, Crystal Structure of, and of Adenine Hydrochloride, J. D. Bernal and D. Crowfoot, 911; B_4 and Adenine, R. D. Heard, H. W. Kinnersley, J. R. O'Brien, Prof. R. A. Peters and V. Reader, 617; C Activity, Indophenol Reducing Capacity of Lemon Juice and its Fractions in Relation to, Dr. S. S. Zilva, 363; and Ascorbic Acid, A. L. Bacharach, 364; Constitution of, Dr. F. Micheel and K. Kraft, 274; E. G. Cox and Dr. E. L. Hirst, 402; in the Adrenal Gland, G. Bourne, 874; Methylnornarcotine, Glycuronic Acid, and, W. J. Dann, 24; Triphenylmethyl Derivative of, L. Vargha, 363
Wave Equations and the Conservation of Energy, A. Lees, 402
Weather, 'Raw', Dr. G. M. B. Dobson; Sir Leonard Hill, 28; 241; Prof. S. Russ, 131; H. E. Beckett, 132
Whale Shark in the Waters Around Ceylon, The, Dr. E. W. Gudger, 165; Dr. J. Pearson, 729
Wheat-Germ Oil: Absorption Spectrum of the Unsaponifiable Matter from, Dr. R. A. Morton and J. R. Edisbury, 618; Vitamin E Fraction of, Absorption Spectrum of the, Dr. P. Bowden and T. Moore, 512
White Pine Blister Rust, Fusion of Pycniospores with Filamentous Hyphæ in the Pycnium in the, R. K. Pierson, 728
Wireless Echoes, Recording, at the Transmitting Station, Prof. S. K. Mitra and H. Rakshit; R. A. Watson Watt and L. Bainbridge-Bell, 657
Wool: Fibres, Origin of Curls and Twists in, Dr. J. E. Nichols, 201; Methionine in, J. Barritt, 689
X-Radiation, Properties of, Prof. C. G. Barkla, 166
γ-Excitation, Mechanism of, by β-Disintegration, Dr. G. Gamow, 57

Corylophidæ (Coleoptera), New Species of, C. Deane, 287
Cosmic: Dust, Increase in Mass of a Planet by the Effect of, F. Zagar (1), 775; Radiation in South Africa, Intensity of, S. M. Naudé and J. E. C. Coventry, 411; Origin of H. Alfvén, 619; (Symons Memorial Lecture), P. M. S. Blackett, 429; Ray Phenomena, Wilson Photographs of, Blackett and Occhialini, 589; Rays: Prof. A. H. Compton, 807; Energy of, Prof. E. Regener, 130; Latitude Variation of, Prof. A. H. Compton, 769; Nature of, Prof. A. H. Compton, 713; Ultra-Radiation, Corpuscular Nature of, Earth-Magnetic Effect and the, Prof. J. Clay, 136
County Maps of England, Early (*Review*), 530
Crustacea, Control of Respiratory Movements in, Prof. H. Munro Fox and M. L. Johnson, 514
Crystal: Lattice Constants, Determination of, by Electron Diffraction, Prof. G. I. Finch and A. G. Quarrell, 842; Structure and Orientation in Thin Films, Prof. G. I. Finch and A. G. Quarrell, 877
Crystalline Style, Oxidase of the, C. Berkeley, 94
Crystals: of the Living Body, Sir William Bragg, 125; Orientation of Certain, by Hydrargillite, L. Royer, 596; Paramagnetic, at Low Temperatures, Principal Magnetic Susceptibilities of Some, Dr. L. C. Jackson, 338; The Form and Properties of, an Introduction to the Study of Minerals and the Use of the Petrological Microscope, Miss A. B. Dale (*Review*), 44; Thermal Expansion in, and Haüy's Law, A. Cavinato 71
Cubic Ferric Oxide, Dissociation of, A. Girard and G. Chaudron, 447
Cuckoo, Swallow and, Arrive, 629
Cuckoo's Call, The, 773
Culture, Science and (*Review*), 707
Cultures, Single-Cell, Transferring, to Solid Nutrient Media, L. O. Kohlmuller and R. Vierthaler, 287
Cuprite, Mono-Crystals of, The Photoelectric Effect in the, R. Deaglio, 887
Cuprous Oxide: in a Magnetic Field, A New Type of Photoelectric Effect in, Dr. I. Kikoin and Dr. M. Noskov, 725; Photo-Cell in Red Light, Reversal of the Current from a, Dr. H. H. Poole and Dr. W. R. G. Atkins, 133
Curare, the Neuro-Muscular Junction and, Tudor Jones, 693
Curlew, Long-billed, Restriction in Range of the, J. W. Sugden, 439
Cyanide-Cyanamide Equilibrium, The, A. Perret and R. Perrot, 375
Cyclades Islands, A New Snake from the, F. Werner, 287
Cyclone Season in the South Indian Ocean, R. A. Watson and N. R. McCurdy, 517
Cyclops, A New Species of, Found at Tenby, D. J. Scourfield, 135
Cynocephalus, Bone of Adult, and of Human Bone, Differential Microscopic Characters of the, Muller and Desmarez, 739
Cytology: Experimental, Third International Congress of, 797; Recent Advances in, Dr. C. D. Darlington (*Review*), 5

Daffodils, Narcissi and their Hybrids, H. W. Pugsley, 517
Dahomey, Rainfall in, Dr. R. Pignol, 208
Dairying, National Institute for Research in, Annual Report for year ending July 31, 1932, 870
Dairy Products, Marketing, Co-operation in, R. W. Bartlett. 2 Vols. (*Review*), 188
Daphnia magna Straus, Antagonistic Action of Ultraviolet Rays on the Phototaxy of, R. J. Wojtusiak, 703
Darwin Where He Did ? Stands (*Review*), 709
Darwin's Barometer, 464

Davainea proglottina, Life-History of the Fowl Tapeworm, F. J. Brown, 276
Davy, Von, und Döbereiner bis Deacon: ein halbes Jahrhundert Grenzflächenkatalyse, Dr. A. Mittasch und E. Theis (*Review*), 150
Deaf and Dumb in England and Wales, 580
Death Valley a National Monument, 542
'Débacle', The, 373
Debye's Dispersion of Nitrobenzene, Prof. J. Weigle and R. Luthi, 327; Theory (formula of Gronwall, La Mer and Sandved), Application of, to solutions of Copper Sulphate, Mlle. M. Quintin, 630
Deep Drilling, New Record for, 721
Definite Integrals with Bessel's Functions, K. Mayr, 703
Dehydro-Ascorbic Acid, Constitution of, Prof. P. Karrer, H. Salomon and K. Schöpp, 800
Delinquency: Constitution Types in, Practical Applications and Bio-physiological Foundations of Kretschmer's Types, Dr. W. A. Willemse (*Review*), 188
Delta Orionis, The Variable Star, Dr. J. Plassmann, 661
Democracy: After, Addresses and Papers on the Present World Situation, H. G. Wells (*Review*), 183
Dental Caries, Cause and Nature of, J. J. Enright, H. E. Friesell, and M. O. Trescher, 918
Depopulation: and Disease, Nutritional Aspects of, Dr. W. M. Strong, 519; The Medical Sciences in Relation to, Dr. R. W. Cilento, 519
De Sitter's World (*Review*), 487
Development Commissioner, Sir William Cecil Dampier appointed a, 581
Devonian Phosphates of Tennessee, Constitution of the, L. Cayeux, 666
Dew Points and Boiling Points of Mixtures of Volatile Liquids, A Boiling Point Apparatus for the Determination of the, L. Gay and J. Soulié, 630
Diabase Rocks at the You Yangs, near Geelong, A. Coulson, 71
Diabetes, The Practical Treatment of, Dr. T. I. Bennett (*Review*), 9
Diamond, Genesis of the, A. F. Williams. 2 Vols. (*Review*), 255
Diamonds, Dr. A. E. H. Tutton (*Review*), 255
Diaporthe, Nits, The Genus, L. E. Wehmeyer, 880
Diatomic Molecules, Band-Spectra of, Dr. W. Jevons; Dr. R. C. Johnson, 102
Diazomethane, Photochemical Decomposition of, Kirkbride and Norrish, 404
Dictyoconoides, *Lockhartia*, and *Rotalia*, The Genera, Col. L. M. Davies, 279
Dielectric Phenomena. 3: Breakdown of Solid Dielectrics, S. Whitehead. Edited, with a preface, by E. B. Wedmore (*Review*), 384
Differential Equations from the Algebraic Standpoint, Prof. J. F. Ritt (*Review*), 456
Differenziali e propagazione ondoso, Caratteristiche dei sistemi, Prof. T. Levi-Civita. Lezioni raccolte dal Dr. G. Lampariello (*Review*), 45
Diffraction Gratings used with Grazing Incidence, O. U. Vonwiller, 668
'Diffusion' and Disease, Dr. C. Nicolle, 879
Diflavones, Synthesis of, J. Algar, Isabella M. McCarthy, and Eveline M. Dick, 666
Dimetaphosphates, Preparation of the, P. Pascal and Mme. Réchid, 666
Diphenyl Series, Crystal Structure of the, Lucy W. Pickett, 513
Diphtheria, Past and Present: its Ætiology, Distribution, Transmission and Prevention, Dr. J. G. Forbes (*Review*), 150
Direction Finding of Birds, An Experiment in, 701
Discontinuous Functions, Effective Integration of, L. Laboccetta (2), 71
Discovery, The Great Age of. Edited by Prof. A. P. Newton (*Review*), 260
Disease: Classical Descriptions of, with Biographical Sketches of the Authors, Prof. R. H. Major (*Review*), 895; The Inborn Factors in, an Essay, Sir Archibald E. Garrod (*Review*), 314
Diselenomesoxanilides and Oxyselenanilides, A. Baroni, 107
Dissociation Formula, A Simple Derivation of the, D. H. Menzel, 739
Dodecolopoda mawsoni, A New Species representing a New Genus of Pycnogonida, Dr. W. T. Calman and Isabella Gordon, 774
Dodo: George Edwards's Picture of the, 615; The, and the Aphanapteryx, G. Renshaw, 728
Donnan Equilibria: The, and their application to Chemical, Physiological and Technical Processes, Dr. T. R. Bolam (*Review*), 859
Dove Marine Laboratory, Report for year ending June 30, 542
Downtonian and Dittonian of Great Britain and North-west Europe, W. W. King, 738
Dragons, G. D. Hornblower, 806
Drink Problem, The Social and Economic Aspects of the (*Review*), 187
Drosophila: Genetic Studies on, 627; *melanogaster*, Genetics of certain Chromosome Anomalies in, A. H. Sturtevant and T. Dobzhansky, 627; *obscura*, Fallen, Spermatogenesis in, C. Koller and Thelma Townson (1), 447
Dublin University, Sir Charles Arthur Kinahan Ball appointed Regius professor of surgery, and Prof. J. Purser professor of civil engineering, 772
Duddell medal of the Physical Society, Award of the, to Prof. W. Gaede, 195
Durham University, Miss Doris L. Reynolds appointed lecturer in geology, 811
Dyes, Anti-Stokes Fluorescence in, Efficiency of, Dr. A. Jabłoński, 839

Early Man in East Africa: 427; 462; Reports of Committees on, 477
Earth: The Common, E. L. G. Watson (*Review*), 636; -Magnetic Effect and the Corpuscular Nature of (Cosmic) Ultra-Radiation, Prof. J. Clay, 136
Earthquake: Alaskan, of April 26, 757; Californian, of March 10, 509; Damage and Earthquake Insurance, Dr. J. R. Freeman (*Review*), 381; in the North of England, 88; in North-west China, 88; in South-east Africa, 19; of March 2, The, C. E. Brazier and L. Génaux; C. Maurain, 596; Series at Nagusa, Japan, A. Imamura, T. Kodaira and H. Imamura, 136; the Californian, 391; the Kansu, of Dec. 26, 304; The Recent Japanese, Dr. C. Davison, 351; Wensleydale, Father J. P. Rowland, 128
Earthquakes: Apparent Velocity of the Surface Propagation of, in relation to the Hypocentral Depth, C. Alessandri, 923; Bibliography of, 580; Destructiveness of (*Review*), 381; Felt and Recorded in Tokyo, Seismometrical Reports on the, 359; in the Holy Land: a Correction, Prof. Bailey Willis, 550; of Northern Africa, Mme. A. Hée, 807; *P* Wave in, Corrections to the Times of the, Dr. H. Jeffreys and K. E. Bullen, 97
East: Anglia, Prehistoric Society of, Annual Business Meeting, Dr. Cyril Fox elected president for 1933, 520; Anglian Flora, The, Prof. E. J. Salisbury, 336
Eclipse of Hi and Ho, Dr. J. K. Fotheringham, 881
Eclipses, Mutual, and Occultations of Jupiter's Satellites, 173
Ecological Studies in Victoria, R. T. Patton (1), 703
Economic: Biologists, Association of, election of officers, 304; Conference, The World, 866; 889; Recovery, Education and, Dr. J. Macmillan Brown, 538; Sanctions, Inadequacy of, Dr. J. J. van der Leeuw, 867
Economics: in Primitive Communities, Prof. R. Thurnwald (*Review*), 315; International (*Review*), 451
Ecuador, New Fossil Fresh Water Molluscs from, W. B. Marshall and E. O. Bowles, 589
Eddy Diffusion, O. F. T. Roberts, 916
Edinburgh University: award of the Cameron prize to Dr. George F. Dick and Dr. Gladys H. Dick, 177; Sir Ian Hamilton installed as Lord Rector, 372; offer of honorary doctorates, 408; Prof. I. de Burgh Daly appointed professor of physiology, 700

Education: and Economic Recovery, Dr. J. Macmillan Brown, 538; for Trades and Industries: a Historical Survey, C. T. Millis (*Review*), 44; The Crisis in, 628
Eels—an Early Hypothesis, 665
Egyptian: Neolithic Barley, A. Jackson, 652; Pottery, Corpus of, 357
Eiffel Tower, Radiation of the Radiotransmitter of the, P. David, 179
Einstein: The Case Against, Col. A. Lynch (*Review*), 260; re review of, Col. A. Lynch, 622
Einsteinian Correction of Time in a Planetary Motion, M. Cimino, 107
Elastic: Electron Scattering in Gases, Dr. S. Werner, 726; Energy Theory, Prof. J. A. van den Broek (*Review*), 347
Elasticity, 'Linked', and its Mathematical Representation, E. Volterra, 107
Electric: Trolley Omnibuses, C. J. Spencer, 869; Welding in Ship Construction, 796
Electrical: Age: The, being further Everyday Marvels of Science, V. H. L. Searle (*Review*), 491; and Rubber Equipment on the Farm, 904; Conductivity and Atmospheric Condensation Nuclei during a voyage to Greenland, C. Maurain and J. Devaux, 35; Energy by Frog-Skin, Output of, W. L. Francis, 805; Engineers, Institution of, Ll. B. Atkinson elected an honorary member of the, 128; awards of the, 723; Equipment of Buildings, Regulations for the, 905; Measurements, Advanced, Dr. W. R. Smythe and Dr. W. C. Michels (*Review*), 322; Resistance, National Standards of, First Comparisons of the, A. Pérard and M. R. Romanowski, 887; Terms: A Dictionary of, including Telegraphy, Telephony and Wireless, S. R. Roget. Second edition (*Review*), 322
Electricity: and Magnetism for Beginners, W. C. Badcock and Dr. E. J. Holmyard (*Review*), 347; Atmospheric, Dr. B. F. J. Schonland (*Review*), 785; Gas and other Fuels as Heating Agents, A. H. Barker, 32; Supply and Distribution, Costs of, J. M. Kennedy and Miss D. M. Noakes, 358
Electrification: of an Ice Factory, J. H. Lamb, 833; of Railways in Britain, F. Lydall, 19; of the Swedish State Railways, Öfverholm, 199
Electrodynamic Forces, Nature of, G. Eibenschütz, 923
Electrolytes (*Review*), 382
Electrolytic: Copper Deposited in the Presence of Colloids, Strains in, P. Jacquet, 70; Dissociation, Rôle of the Solvent in, Dr. A. R. Martin, 584; Dr. J. A. V. Butler and Miss L. C. Connell, 800
Electromagnet, A Compact, for General Purposes, Dr. L. F. Bates and B. J. Lloyd Evans, 558
Electrometer Triode in the X-ray Ionisation Spectrometer, Dr. W. A. Wooster, 545; Dr. B. W. Robinson, 546
Electron: Diffraction: by Films of Grease, Prof. G. P. Thomson and C. A. Murison, 237; by Vapours, Dr. H. de Laszlo, 803; Energy of the Beams in, Prof. R. Whiddington and F. C. Poultney, 814; Inelastic Scattering in Gases, C. B. O. Mohr and F. H. Nicoll, 143; Motion of an, in a Crystalline Lattice, G. C. Wick, 71; Polarisation? Prof. R. Whiddington, 908; Positive, A Possible Property of the, Dr. W. Elsasser, 764; Scattering by Atoms, Further Calculations of, Massey and Mohr, 368; Polarisation Phenomena in, E. Rupp, 209
Electronic Oscillations, Production of, with a Two-Electrode Valve, J. S. McPetrie, 691
Electrons: in Amorphous and in Crystalline Antimony, Diffraction of, J. A. Prins, 760; in Gases, Large Angle Scattering of, C. B. O. Mohr and F. H. Nicoll, 143; in Helium: at Zero Angle, Inelastic Scattering of, Prof. R. Whiddington and J. E. Taylor, 814; Scattering of, Prof. R. Whiddington and T. Emmerson, 814
Electrophoresis, A Correct Arrangement for, Mlle. Choucroun, 630
Electrostatic Precipitation, Direct-Current Generators for, 162
Elektrischen Ladung der Erde, Die Aufrechterhaltung der, Prof. E. Schweidler (*Review*), 785
Elektrolyte, Prof. H. Falkenhagen (*Review*), 382
Elements: Artificial Transmutation of the (Boyle lecture), Lord Rutherford, 832; Chemical Detection of, Prof. F. A. Paneth and P. L. Günther, 652; Light, Disintegration of, by Fast Protons, Dr. J. D. Cockcroft and Dr. E. T. S. Walton, 23; Small Quantities of, Spectroscopic Detection of, W. Späth, 30; Transmutation of the, Recent Researches on the, Lord Rutherford, 388
Elvers, Arrival of, 409
Empire: Broadcasting, 16; Forestry Handbook, new edition, 870; *Journal of Experimental Agriculture*, 304; No. 1, 759; Timbers for Structural Design. British Columbia Douglas Fir, 244
England: The Map of, or About England with an Ordnance Map, Col. Sir Charles Close (*Review*), 260
English Language: Use of the, Dr. C. Norwood, 197; 741
Entomological Society of London, The History of the, 1833–1933, Dr. S. A. Neave, assisted by F. J. Griffin (*Review*), 678
Enzyme which dehydrogenates Stearic Acid, Presence in the Bile of an, G. Quagliariello, 411
Enzymes: A Discovery and its Consequences, Dr. E. F. Armstrong, 535
Eremophila Mitchelli, Essential Oil from the Wood of, A. E. Bradfield, A. R. Penfold, and J. L. Simonsen, 667
Ergosterol and Cholesterol, Hydroxyl Group in, Prof. I. M. Heilbron and J. C. E. Simpson, 438
Eros, Mass of, Dr. K. Lundmark, 31
Erysiphe graminis Tritici, Host Specialisation of, E. B. Mains, 739
Eskimo: Culture Sequence, J. A. Ford, 243; in Greenland, Spread of, Capt. E. Mikkelsen, 367; Vertebræ, Anomalous, Dr. T. D. Stewart, 125
Essential News, 614
Ethane, Slow Combustion of, at High Pressures, D. M. Newitt and A. M. Bloch, 214
Ethics and Archæology, 561
Ethnogenics, Capt. G. Pitt-Rivers, 89
Ethyl Alcohol and Ethyl Ether, Freezing Points of Binary Mixtures of, A. Lalande, 447
α-Ethylene Oxides, Some, R. Lespieau and Mlle. B. Gredy, 447
Eucalypts, Chemical Composition of the Woods of the Ironbark Group of, W. E. Cohen, A. L. Baldock, and A. G. Charles, 333
Eucalyptus, Identification of the Coloured Woods of the Genus, H. E. Dadswell and Maisie Burnell, 280
Eugenics and Marriage Laws, L. M. Crump, 540
Europe: Northern, Spring in, 812; Southern, Dr. Marion I. Newbigin (*Review*), 317
Evelyn's "Fumifugium", Reprint of, 651
'Events', 'Time' and, Ideas of, W. W. L., 727
Everest: Mount, Col. H. L. Crosthwait, 10; Flight, Preliminary Tests for, 160; Projected Flight over, 392; Houston Expedition over, 499
Evolution: and Philosophy, Prof. R. R. Gates (*Review*), 380; Creative, The Mechanism of, Dr. C. C. Hurst (*Review*), 780; Taxonomy and, Dr. W. H. Longley, 863; The Causes of, Prof. J. B. S. Haldane (*Review*), 709; The Scientific Basis of, Prof. T. H. Morgan (*Review*), 380; Up to Date (*Review*), 780
Examination Methods, Committees on, 141
Exchange of Goods during Economic Depression, 834
Exhibition of 1851, appointments to Senior Studentships, 848
Experimentalphysik, Handbuch der, Herausgegeben von W. Wien und F. Harms. Unter Mitarbeit von H. Lenz. Band 4: Hydro- und Aerodynamik. Teil 4: Rohre, Offene Gerinne, Zähigkeit. Herausgegeben von L. Schiller. Bearbeitet von L. Schiller, F. Eisner, S. Erk (*Review*), 602
Explosion Flames, Photographic Analysis of, Prof. W. A. Bone, 300
Explosions, Experimental, Air Waves from, Dr. F. J. W. Whipple, 138

Explosive Chain Reaction: between Hydrogen and Oxygen, Upper Pressure Limit in the, C. N. Hinshelwood and G. H. Grant, 361; Upper Limit in, H. W. Melville and H. L. Roxburgh, 690
Explosives: Chemical Examination of, A. Marshall (*Review*), 186; Their History, Manufacture, Properties and Tests, A. Marshall. Second edition. Vol. 3 (*Review*), 452; War and Post-War, Prof. R. C. Gale (*Review*), 452
Exponential and Hyperbolic Functions, The, and their Applications, A. H. Bell (*Review*), 319
Extra-Galactic Nebulæ, The, Dr. H. Knox-Shaw, 247
Extreme Ultra-Violet, Studies in the, and the very soft X-ray Region, Prof. M. Siegbahn (Guthrie lecture), 901
Eyes and Colour Change, Prof. Ll. M. Bertholf, 331

Fabrication, An Intentional, of an Engraving of a Horse's Hoof on Granite, by means of a Stone Tool, M. Badouin, 375
Facial Growth in Children, Corisande Smyth and M. Young, 29
Fact, Convention and, Dr. N. R. Campbell, 237
Faith, Hope and Charity in Primitive Religion, Dr. R. R. Marett (*Review*), 9
Faraday Effect of a Camphor Derivative, J. Verhaeghe, 666
Faraday House Journal, 466
Farm, Electrical and Rubber Equipment on the, 904
Fat in Æstivating Animals, 268
Fauna of Hot Springs in North America, C. T. Briers, 403
February Fill-Dyke, 141
Feldspäte, Die, und ihre praktische Bestimmung, Dr. K. Chudoba (*Review*), 384
Ferns, Sporangia containing Spermatozoids in, Alice E. Gairdner, 621
Ferromagnetics, Atomic Moments of, Dr. E. C. Stoner, 433
Ferro-Silicons Rich in Silicon, Magnetic Susceptibility of, C. Bedel, 375
Ferrous Metals and Alloys, Cast, Sampling and Analysis of, 845
Fibres from the Coat of a Blackface Lamb, Dr. S. G. Barker, 799
Fifty-five Year Rule, The, 146
Film Institute, A British, 465
Filter for the 3130 Mercury Line, A Method of Preparing a, G. C. Brock, 410
Fire, Safety of Life from, Col. G. Simonds, 269
Fish: and Fishing (*Review*), 42; Cultivation in the Philippines, 522; Culture, 177; Movements, Directional Control of, Dr. J. Gray, 774; Species (Cyprinides), Three New, from Asia Minor, V. Pietschmann, 704
Fishery Research: Advisory Committee on, of the Development Commissioners, Prof. E. W. MacBride appointed chairman of the, 871; in Newfoundland, 918
Fishes, Muscular Movements of, Dr. J. Gray, 825
Flies Go in Winter? Where do, 249
Flight: 'Instrumental', Stability of, G. A. Crocco, 71; Non-stop, New Record for, Squadron-Leador O. R. Gayford and Flight-Lieut. G. E. Nicholetts, 232
Flint Miners of Blackpatch, The, J. H. Pull (*Review*), 677
Flood-Lighting and Bird-Life, 55
Flora: of Surrey, late C. E. Salmon. Edited by Dr. W. H. Pearsall (*Review*), 77; The East Anglian, Prof. E. J. Salisbury, 336
Flow Kinetics: Model of Photolysis, E. Abel and H. Schmid, 251
Flower-Size, Inheritance of, Prof. R. R. Gates, 136
Fluorescence, Negative Polarisation in, K. S. Krishnan and S. M. Mitra, 204
Fluorescent Screens, the Spurious Ring Exhibited by, J. V. Hughes, 558
Fluorite from Obira, Japan, Bands in the Thermoluminescent Spectrum of, Ei-ichi Iwase, 909
Fluorites, Luminescence Investigations with, (2), H. Haberlandt, 851
Flyfisher, The, and the Trout's Point of View, Col. E. W. Harding (*Review*), 42
Fly Swarms in Dwelling Houses, Composition of, 249
Fog Droplets, Size of, M. Kinoshita and K. Uchiyama, 99
Food: Consumption after Fasting, Capacity for, V. Famiani, 339; Relation of, to Disease, S. Dixon, 333; Storage at Low Temperature, Sir William Hardy (Hunter Memorial Lecture; Sir William Trueman Wood Lecture), 459; Value, Reconstructive, of the Embryos of Various Cereal and Leguminous Seeds, V. Famiani, 339
Foods, The Structure and Composition of, Dr. A. L. Winton and Dr. Kate Barber Winton. Vol. 1 (*Review*), 316
Forest: Fires: and Weather, T. Terada and T. Utigasaki, 161; in relation to Soil Fertility, Prof. F. P. Worley, 787; on the Roof of the (*Review*), 78; Products Research Board, Report for 1931, 847
Forestry: British, Problems of, Prof. R. S. Troup, 900; Commission, Twelfth Annual Report, 406
Formaldehyde in Dew, Presence of, Prof. N. R. Dhar and Atma Ram, 800
Forthcoming Books of Science, 322
Fossil: Bones: Bakelite Impregnation of, H. W. Nichols and P. C. Orr, 127; Preservation of, L. McL. Mann, 366; W. J. McCallion, 694; Mammals, Some Ancestral (*Review*), 454
Fossiliferous Deposits in the Homa-Kendu Area, Kenya Colony, Dr. L. S. B. Leakey, 886
Fourier Analysis and Vowel Curves, R. H. Nisbet, 401
Fowl, Non-Disjunction in the, Prof. F. A. E. Crew, 446
François Joseph Archipelago, Circumnavigation of the, by the North, J. Schokalsky, 70
Franklin Institute, award of medals to Dr. Orville Wright, Dr. P. Sabatier and J. de la Cierva, 870, 871
Franz Josef Land, Voyage around, Prof. N. N. Subov, 359
Frazer Lectures, The, 1922–1932, by divers hands. Edited by W. R. Dawson (*Review*), 712
French: Chemical Society, Annual Meeting of the, 870; Society of Physical Chemistry, 25th anniversary of the, 797
Freshwater Biological Association, election of officers, 796
Frog, Hermaphrodite, A. A. M. Gardiner, 330
Frogs: and Fishes, Showers of, 666; Hibernation of, 34; Spawning in, Factors Controlling date of, R. M. Savage, 587; Spawning of, and a remarkable Tadpole, 521
Frost and Shore Animals, 142
Froude, William, Laboratory, Ship Researches at the, 162
Fruits, Hardy, Trials of Varieties of, for Commercial Purposes, 63
Fuel: Gas, Water and Lubricants, The Analysis of, Prof. S. W. Parr. Fourth edition (*Review*), 860; -Knock, A Theory of, Dr. S. Steele, 724; Research Board, Report for year ending March 31, 1932, 627; Testing: Laboratory Methods in Fuel Technology, G. W. Himus (*Review*), 259
Fulminating Material, E. Mathias, 482
Fundulus, Xanthophores in, A. E. Warren, 287
Fur-Bearing Animals in Michigan, Dr. N. Dearborn, 127
Furunculosis, 213
Furze or Gorse (*Ulex europæus*) Flowering, 34

G., The Constant of Gravitation, Prof. V. V. Narlikar, 134
γ-Excitation by β-Disintegration, Mechanism of, Dr. G. Gamow, 57
γ-Rays: Anomalous Absorption of, B. Arakatsu, 696; Internal Conversion of, Hulme; H. M. Taylor and Mott, 99; Ellis and Mott, 517
Gafsa Hills, Tunisia, Pleistocene Dating of, R. Vaufrey, 659
Galactic: Co-ordinates, Tables for, J. Ohlsson, 100; Dimensions, H. Shapley, 739; Rotation, Miss Phyllis Hayford, 173
Galaxy, Absorption of Light in the, Prof. J. Stebbins and Dr. C. M. Huffer, 769
Gallium Isotopes 69 and 71, Nuclear Moments of the, J. S. Campbell, 204
Gammarus chevreuxi, Sexton, Further Mutations in the Amphipod, Mrs. E. W. Sexton and Miss A. R. Clark, 201
Gannets, Return of the, 373

Garnet in the Dartmoor Granite: its Petrogenetic Significance, A. Brammall and S. Bracewell, 250
Gas, Use of, Development of the, S. Lacey, 478
Gases: Conductivity of Mixtures of, Dr. S. P. McCallum and L. Klatzow, 841; Rare, Discovery of the, Prof. M. W. Travers, 65
Gaseous: Combustion: at High Pressures, Prof. W. A. Bone, and others, 245; Researches on, Prof. W. A. Bone (Bakerian lecture), 494; Hydrogen Iodide, Action of, on some Iodine Derivatives of Hydrocarbons, G. Emschwiller, 738; Ions at Cathodes, Accommodation Coefficient of, K. T. Compton, 631; Oxidation, A. Ritchie and Ludham, 64; Tubes for Lighting, J. N. Addington, 235
Gastropods: Crystalline Style in, Prof. C. M. Yonge, 915; Style-Sac of, R. V. Seshaiya, 30
Gaza, Old, Sir Flinders Petrie, 868
Geddes's Comet, 441
Gegenschein, The, or Counterglow, Dr. C. T. Elvey, 590
Genetical Studies, Modern (*Review*), 185
Gentleman, A Very Gallant, Commdr. L. C. Bernacchi (*Review*), 782
Genus *Lolium*, Nitrogen Fixation in the, B. Brown, 169
Geographical: Association, Annual Conference of the, Dr. L. D. Stamp, 68; Names, Foreign, Report on, 161
Geography, An Approach to, Dr. H. R. Mill, 68
Geological: Society of London, awards of the, 159; award of the Daniel-Pidgeon fund to J. D. Solomon, 616; election of officers, 432; Survey of Great Britain, Summary of Progress for 1930, 370
Géologie et les mines de la France d'outremer, La (*Review*), 823
Geologische Erforschung Thüringens in älterer Zeit: Die, ein Beitrag zur Geschichte der Geologie bis zum Jahre 1843, Prof. B. von Freyberg (*Review*), 531
Geology: and Glaciation of some Islands of the Southern Ocean, etc., Sir Douglas Mawson, 847; and Petrology of the Mount Leinster district, North-east Victoria, E. Broadhurst and J. D. Campbell, 703; and Physical Geography, A French–English Vocabulary in, G. M. Davies (*Review*), 604; Economic, Aerial Survey in Relation to, D. Gill; H. Hemming, 160; in Great Britain, 370; in the Life of a Nation, The Place of, Dr. L. L. Fermor; Dr. L. D. Stamp, 226
Geometry: Coordinate, A Treatise on (*Review*), 603; Coordinate, Elements of, J. M. Child (*Review*), 603
Geophysical Prospecting, 791
Geophysics, The Contribution of Radiotelegraphy to, 642
Georgia and its People (*Review*), 309
Georgian People: A History of the, from the Beginning down to the Russian Conquest in the Nineteenth Century, W. E. D. Allen (*Review*), 308
Geothermic Gradient in Limagne, G. Grenet, 143
German: Chemical Plant Exhibition ('Achema VII'), 1934, 907; Universities, Resignation of Jewish Professors, 687
Gestalt Theory, The, and the Problem of Configuration, B. Petermann, translated by M. Fortes (*Review*), 604
Glabratic Acid, G. Koller and G. Pfeiffer, 411
Glasgow, Royal Technical College, Report of, 213
Glasshouses, Disinfection of, with Sulphur, W. H. Read and O. B. Orchard, 844
Glauconite in Limestone, Modes of Existence of, L. Cayeux, 143
α-Glucoheptulite, Identification and Biochemical Oxidation of, Mme. Y. Khouvine and G. Nitzberg, 339
Glucose: and Shedding the Shell of Crustaceans, Mme. Andrée Drilhon, 483; Metabolism, Glutathione, Iodoacetic Acid and, Dr. J. H. Quastel, 206
Glucuronic Acid, A New Unsaturated Derivative of, J. Pryde and R. T. Williams, 57
Glutathione, Iodoacetic Acid and Glucose Metabolism, Dr. J. H. Quastel, 206
Glyceria aquatica, Hydrocyanic Acid in, P. Guérin, 106
Glycogen: in Cartilage, Dr. H. B. Fell and Dr. R. Robison, 62; Triacetate, W. S. Reich, 106
Glycuronic Acid, Methylnornarcotine, and Vitamin C, W. J. Dann, 24
Gob Fires, Experimental, T. N. Mason; F. V. Tideswell, 521
God, Existence and Nature of, A Study of the Ordinary Arguments for the, Rev. A. C. Bouquet (*Review*), 677
Gold: in Kenya: 231; and Native Reserves, 37; -bearing strata of the Region of St. Yrieix (Haute-Vienne), Wakker, 483; Organic Compounds of, Prof. C. S. Gibson, 130
Gonad-stimulating Hormones in Hypophysectomised Animals, Prof. J. B. Collip, Dr. H. Selye, and Prof. D. L. Thomson, 56
Gondwanaland, Land Bridges of, Prof. C. Schuchert, 696
Gordon, Genl., and the Double Coconut, 337
Gorgonacea from the Great Barrier Reef, Prof. S. J. Hickson, 879
Government Chemist, Work of the, 246
Grain Conference, World, 758
Granary, A Modern, 431
Grass: -Land, Manuring of, 373; Silage, C. Boyle and J. J. Ryan, 410
Graticules, Photographic, Sir Herbert Jackson, 766
Gray, Thomas, Memorial Trust, awards under the, 359
Great: Bear Lake Indians, Dr. C. M. Osgood, 623; Crested Grebe in Britain, Spread of the, T. H. Harrisson and P. A. D. Hollom, 135
Greenkeeping Research, 272
Green Plants in a Confined Atmosphere, Life of, J. Beauverie and Mlle. S. Monchal, 36
Greenland: East, New Map of, 90; Ice, Thickness of the, Dr. E. Sorge, 807; Total Calorific Radiation in, C. Maurain and J. Devaux, 106
Greenwich, Royal Observatory, Annual Visitation, 882
Grid: in Great Britain, Completion of the, 539; the French, 539
Grouse, Red, Migration of, 579
Growth, Influence of Living-Space upon, Dr. J. Podhradsky, 29
Guatemala, Mexico and, Recent Discoveries in, 101
Guébhard-Séverine, Annales, No. 8, 797
Guggenheim, Daniel, medal, award of the, to Commdr. J. C. Hunsaker, 871
Guiana Forest, A Naturalist in the, Major R. W. G. Hingston (*Review*), 78
Gulick: John Thomas, Evolutionist and Missionary, portrayed through documents and discussions, A. Gulick (*Review*), 532
Gypsy Art in Russia, M. A. Barannikov, 271
Gyrocotyle, Development of, J. S. Ruszkowski, 243
Gyrostats, Self-Erecting, Prof. J. G. Gray, 250

H-rays in Different Gases, Ionisation of, J. Schintlmeister, 251
Halley's Comet: in 1909–11, Dr. A. C. D. Crommelin, 282; N. T. Bobrovnikoff, 282
Halley, Edmond: Dr. A. Ferguson, 153; Correspondence and Papers of, Arranged and edited by E. F. MacPike, 153
Halogens in Organic Substances, Estimation of the, by the Sodammonium Method, F. Govaert, 179
Hancock's Steam Omnibus, Centenary of, C. E. Lee; C. F. D. Marshall, 647
Harrison Memorial Prize, award of the, to Dr. H. J. Emeléus, 91
Harrison's First Marine Timekeeper, 355
Harvard University: Dr. J. B. Conant elected president of, 700; Physics at, 395
Harveian Oration, 1932, Sir George Newman, 407
Harvey: and Preventive Medicine, 407; and the College of Physicians, The Debt of Preventive Medicine to, Sir George Newman, 407
Haut-Katanga: Petrographical Researches in the, M. Gysin, 411; (2), 815; (3), 887
Hawaii, Kepelino's Traditions of, edited by Martha Warren Beckwith, 474
Hawaiian Feathercape, H. G. Beasley, 171
Hearing: Evolution and Mechanism of (*Review*), 147; in Man and Animals, Dr. R. T. Beatty (*Review*), 147; Tests of, 163
Heart, Abnormal Movability of the, S. Osawa, 241

Heat: in Air, Natural Convection of, when the heating is very small, P. Vernotte, 179; Transmission of, through Fabrics, M. C. Marsh, 558

Heating: Agents, Electricity, Gas and other Fuels as, A. H. Barker, 32; and Ventilating Engineers, Institution of, *Journal* of the, March, 541

Heathen Baptism in Early Britain, Miss Eleanor Hull, 403

Heaviside Layer, New Observations on the, Ratcliffe and White, 807

Helm or Steering Orders, The New, 20

Helminosporium avenæ, Sporulation of, in Artificial Culture, W. A. R. Dillon Weston, 435

Helium: Beryllium and, Lord Rayleigh, 724; Liquefaction Plant at the Clarendon Laboratory, Oxford, Prof. F. A. Lindemann and T. C. Keeley, 191

Heredity and Hibernation in Insects, 249

Herring Fishery off East Anglia, Forecasting the, Dr. W. C. Hodgson, 98

Herrings: and the Origin of Petroleum, 578; Icelandic, Food of, Dr. P. Jespersen, 884

Hertzian Domain, Dispersion in the, J. Weigle, 144

Heteroazeotrope, The Ternary, W. Swietoslawski and E. Wardzinski, 887

Heterochrome Photometry of Incandescent Lamps, Solution of the Problem of, G. Ribaud, 667

Heterodera schachtii, the Potato Eelworm, J. Carroll, 850

Hexafluorides of Sulphur, Selenium and Tellurium, Structures of the, L. O. Brockway and L. Pauling, 739

Hexane, Action of Steam on, C. Matignon and M. Séon, 286

'Hexuronic: Acid' (Ascorbic Acid) as the Antiscorbutic Factor, Prof. A. Szent-Györgyi and Prof. W. N. Haworth, 24; and its Chemical Determination, T. W. Birch, Dr. L. J. Harris, and S. N. Ray, 273; W. J. Dann, 274

Hibernium Halos, Formation of, Radioactivity of Samarium and the, Dr. H. J. H. Poole, 654

High: -Frequency Currents produced by High-Tension Magnetos, J. Jaffray, 559; Discharge in Gases, T. V. Ionesco and Mme. Irène Mihul, 887; J. C. Wilson, 546; Precision Levelling, Influence of the Daily Oscillations of the Vertical on the Results of, E. Prévot, 559; Pressure Boilers, C. H. Davy and C. H. Sparks, 90; Research, Prof. P. W. Bridgman, 280; The Physics of, Prof. P. W. Bridgman (*Review*), 259; Selectivity Tone Corrected Receiving Circuits, F. W. Colebrook, 442; Voltages, Electrostatic Production of, Van de Graaf, Compton, and Van Atta, 475

Highway Research, Developments in, Prof. Steinburg, 334

Hindu Metal Images, Dr. F. H. Gravely and T. N. Ramachandran, 279

Hispine Beetles, Early Stages of, S. A. Maulik, 171

History: as Science, 525; in Science, 777

Hochelaga, Plan of, W. D. Lighthall, 64

Hochwipfel Strata of the Carinthian Alps, A Fauna from the, K. Metz, 287

Hæmolytic Streptococci: The, their Grouping by Agglutination, late Sir Frederick W. Andrewes and Ethel M. Christie, 593

Honduras, South-Eastern, Archæological Expedition to, 650

Hong-Kong, Climate of, T. F. Claxton, 104; Col. E. Gold, 236

Hormones, Gonad-Stimulating, in Hypophysectomised Animals, Prof. J. B. Collip, Dr. H. Selye and Prof. D. L. Thomson, 56

Horticultural Education Association, Year Book of the, 1932, 616

Houston Expedition over Everest, 499

Huddersfield Technical College, Work of the, 557

Human Reflexology: General Principles of, an Introduction to the Objective Study of Personality, Prof. V. M. Bechterev. Translated by Emma and W. Murphy (*Review*), 675

Hume, David, Dr. B. M. Laing (*Review*), 321

Humidity Tables, Negretti and Zambra, 589

Humour and Humanism in Baeyer's Laboratory, Prof. J. Read, 294

Hurricanes of the Southern Hemisphere, 34

Huxley and Scientific Education (Huxley Memorial Lecture), Prof. H. E. Armstrong, 684

Hydra, Nerve-Net of, C. H. McConnell, 207

Hydro- and Aerodynamics (*Review*), 602

Hydrocarbon: Combustion in an Engine, A. Egerton and F. Ll. Smith, 725; Vapours, Polarity of, McAlpine and Smyth, 517

Hydrocarbons Produced by the Action of Indene on Fatty Organomagnesium Derivatives, Velocity of Disengagement of, D. Ivanoff and I. Abdouloff, 483

Hydrocephalus, a Hereditary Character in the House Mouse, F. H. Clark, 288

Hydrochloric Acid, Influence of Temperature on the Absorption of Aqueous Solutions of, in the Extreme Ultra-Violet, R. Trehin, 179

Hydrodynamics: Sir Horace Lamb. Sixth edition (*Review*), 313; Evolution of, Dr. H. Jeffreys (*Review*), 313

Hydrogen: and Chlorine, Photochemical Reaction of, Prof. H. B. Baker, 27; Prof. A. J. Allmand, 656; and Oxygen: in a Silver Vessel, Combination of, C. N. Hinshelwood, E. A. Moelwyn-Hughes and S. C. Rolfe, 142; Reaction between, C. N. Hinshelwood, E. A. Moelwyn-Hughes and S. C. Rolfe, 625; Electrode, Improvements to the, for the Measurement of Hydrogen Ion Concentration in Solutions, P. Lecomte du Noüy, 179; Isotope, G. N. Lewis, 590; on Mercury, Initial Electrolytic Over Voltage in the Disengagement of, R. Dufour, 482

Hydrogenations, Catalysed, Velocity of, A. Kailan and O. Stuber, 251

Hydronomics: Report of the Committee on, Division of Physical Sciences, National Research Council (*Review*), 112; (*Review*), 112

Hydroxyl Group: in Ergosterol and Cholesterol, Prof. I. M. Heilbron and J. C. E. Simpson, 438; The, and Soap Film Structure, W. J. Green, 873

Hygrometer, The Wet-and-Dry Bulb, F. J. W. Whipple, 374

Hygroscopy: Capacitance, Dr. W. L. Balls, 329; Capacitance, and Some of its Applications, Dr. R. K. Schofield, 96

Hyper-Elliptic Surfaces from the Real Point of View, Classification of, S. Cherubino, 339

Hyperfine Structure and Nuclear Moments, Prof. B. Venkatesachar and L. Sibaiya, 844

'Iberomarusian', E. G. Gobert and H. Vaufrey, 367

Ice Bridge, The: 557; A Correction, 921

Iceland Spar, Pleochroism of, P. Le Roux, 447

Ideal Home Exhibition, Science at the, 500

Ideas, Adventures of, Prof. A. N. Whitehead (*Review*), 746

Ignition-Coil Discharge Characteristics, Control of, Prof. G. I. Finch and R. W. Sutton, 374

Illuminated Fountains, A. S. E. Ackermann, 396

Immiscible Liquid Layers, Systems of, Four, E. Lester Smith, 167

Impulse Generator, A New, for Three Million Volts, T. E. Allibone, F. S. Edwards and D. B. McKenzie, 129

Incentives in Industry, The Problem of, Dr. G. H. Miles (*Review*), 321

Index Veterinarius, No. 1, 906

India: 1931, The Census of, 109; Age of Retirement in, 146; Mechanical Transport in, Col. F. P. Barnes, 578; Mother Goddess in, Kalipada Mitra, 207; South: Prehistoric Gold-Mining in, L. Munn, 730; -West Monsoon in, 812; Wild Life in, Preservation of, 779

Indian: Association for the Cultivation of Science, Appointment of K. S. Krishnan as secretary and Mahendral Sircar research professor in physics, 907; Caste Customs, L. S. S. O'Malley (*Review*), 638; Federation, 427; Hot Weather, 701; Institute of Science, Bangalore, 607; Progress at the, 834; Microlepidoptera, Life-Histories of, T. B. Fletcher, 474; Philosophy, A History of, Dr. Surendranath Dasgupta. Vol. 1. Second edition. Vol. 2 (*Review*), 855; Outlines of, M. Hiriyanna (*Review*), 855; Sage,

An, Prof. H. E. Armstrong (*Review*), 672; Sleeper Woods, Identification of, K. A. Chowdhury, 30; Thought, The Development of, Dr. T. Greenwood (*Review*), 855; Tribe, The Changing Culture of an, Dr. Margaret Mead (*Review*), 711; Woods, Calorific Values of, S. Krishna and S. Ramaswami, 281
Indices of a Stable Population, Prof. R. Firth, 519
Industrial: Administration, Institute of, 395; Aluminas, Velocity of Dissolution of, in Fused Cryolite, N. Parravano and O. D'Agostino, 107; Management, Specialist Posts in, Dr. W. H. Coates, 268; Psychology in Practice, H. J. Welch and Dr. G. H. Miles (*Review*), 567; Research, Co-operative, 817
l'Industrie Nationale, Société d'Encouragement pour, award of the medal of the, to P. Chevenard, 867
Industry: The Arts in, 73; The Management Factor in, 52
Infestation of Stored Products by Insects, Prof. J. W. Munro, 82
Influenza: March of, 22; Spread of, 128
Infusoria, Ciliated, Axial Gradient in the, J. Monod, 339
Insect-Eating in Siam, W. S. Bristowe, 234
Insects: and Micro-Climates: Dr. H. H. Darby, 839; H. S. Leeson and K. Mellanby, 363; Inhabiting the Soil Surface, Dr. J. Davidson, 837
Institut Colonial International: Great Britain and the Conferences of the, Prof. B. Williams, 683; Lord Lugard elected president of the, 683
Integral Radiator (Black Body), of Electrically Heated Carbon, T. N. Panay, 179
Intelligence in Man, Inheritance of, A. F. Dufton, 763; Dr. C. C. Hurst, 764
Intensities, Relative, Direct Recording of, by means of a Microphotometer, N. Thomson, 558
Interaction between Different Species of Animals, The Quantitative Theory of, V. A. Bailey, 524
Interatomic Distances and Ferromagnetism, E. C. Stoner, 814
Internal Ballistics, The Combustion Problem of, Dr. A. D. Crow and W. E. Grimshaw, 805
International: Auxiliary Languages, Dr. E. Ritter, 102; Congress: for Applied Mechanics, The Fourth, 907; of Scientific and Applied Photography, 212; Ornithological Congress, The Eighth, 902; Relations: The Background of, Our World Horizons, National and International, Prof. C. Hodges (*Review*), 45
Invar, Dr. Ch.-Ed. Guillaume, 658
Invertebrates (*Review*), 76
Invertebrata: The, a Manual for the Use of Students, L. A. Borradaile and F. A. Potts. With chapters by Prof. L. E. S. Eastham and J. T. Saunders (*Review*), 76
Iodine: Arc Spectrum of, Prof. W. E. Curtis, 398; Atomic Weight of, Guichard, 738; -Oxalate Reaction, Kinetics of the, Prof. N. R. Dhar, A. K. Bhattacharya and B. L. Mukerji, 840; Tincture of, and Asepsis, R. Sorel, 596; Vapour at High Temperatures, Absorption Bands of, E. Skorko, 366
Iodoacetic Acid, Glutathione and: Glucose Metabolism, Dr. J. H. Quastel, 206; and Tissue Glyoxalase, Dr. F. Dickens, 130
Iodo-Silver-Benzoic Complex, An, and its Application to the Oxidation of Ethylene Compounds into α-Glycols, C. Prévost, 774
Ionisation Produced by Radioactive Sources, Amplification of the, J. A. C. Teegan, 277
Ionised Gases in the Magnetic Field, T. V. Ionescu and C. Mihul, 106
Ionization in Cable Dielectrics, P. Dunsheath, 404
Ionosphere: Characteristics of the, J. P. Schafer and W. M. Goodall, 804; Fine-Structure of the, Prof. E. V. Appleton, 872; J. A. Ratcliffe and E. L. C. White, 873; Wireless Investigations of the, An Automatic Recording Method for, C. T. R. Wilson, J. A. Ratcliffe and E. L. C. White, 522
Ions: Gaseous, Prof. A. M. Tyndall, 65; Monovalent, Limiting Mobilities of Some, and the Dissociation Constant of Acetic Acid at 25°, Dr. A. I. Vogel and G. H. Jeffery, 27; Multiply-Charged Large, J. J. Nolan and J. G. O'Keeffe, 106
Iraq: Northern, Expedition to, 89; Petroleum and Pipe-Line, 864
Ireland, Anthropological Survey of, 160
Iris, Physiology of the, (1), J. Z. Young, 178
Irish: Flora and Fauna, Origin of the: Dr. R. Lloyd Praeger, 279; 579; Plants, Some Noteworthy, Dr. R. Lloyd Praeger, 172; Woods and their Significance, A. C. Forbes, 246
Iron and Steel: Industry, The, Sir William Larke, 335; Institute, K. Headlam-Morley appointed secretary of the, 272; Cast, Analysis of, 845; -working in the Bahr el Ghurzal, T. C. Crawhall, 474
Isotopes: of the Radio Elements, 440; Zero-Point Energy and the Separation of, H. Eyring, 739
Israel: from the Beginnings to the Middle of the Eighth Century, Prof. A. Lods. Translated by Prof. S. H. Hooke (*Review*), 315
Isthmian Links, Prof. B. Willis, 696

January freeze-the-pot-by-the-fire, 34
Japan Sea Floor, Lowering of the, Prof. H. Tsuya, 368
Japanese: Journal of Engineering, Vol. 8, 543; Physiological Standards and Occupational Characteristics of Bodily Functions of the, Tomoyosi Isikawa, 588; Power Station, A Modern, 127
Jehol: City of Emperors, Sir Sven Hedin. Translated by E. G. Nash (*Review*), 184
Jews in Germany, 612
Jupiter, Seasonal Changes on, A. S. Williams, 808

Kaiser Wilhelm Gesellschaft, Work of the, 870
Kamet Conquered, F. S. Smythe (*Review*), 224
Kangaroo Mouse of Western America, 737
Karyology and Systematic Relationship, 807
Katabatic Winds, S. Atmanathan, 696
Kattegat, Boundary Tides in the, H. Pettersson and B. Kullenberg, 586
Kazakstan, Semipalatin District of, Rodents of the, B. A. Kuznetzov, 516
Kea Parrot, The, 463
Kennelly-Heaviside Layer: Prof. E. V. Appleton and R. Naismith, 808; Polarisation of Echoes from the, T. L. Eckersley, 512
Kenya: Gold in, and Native Reserves, 37; 123; 231; Miners' 'Claims' and Native Lands in, 51
Kerr Cell, The, E. E. Wright, 702
Ketene, Sudden Pyrogenation of, J. A. Muller and Mlle. Eglantine Peytral, 375
Kidston Collection of Fossil Plant Slides (2), Mary G. Calder, 922
Kitchen-Middens at Gordon's Bay, H. A. Shapiro, 411
Knowledge: and Action, 485; and Existence, The Theory of, Dr. W. T. Stace (*Review*), 455
Kosmos, Prof. W. de Sitter (*Review*), 487
Kuala Selinsing, Perak, Excavations at, I. H. N. Evans, 135
Kudaru Hills, Nigeria, Younger Intrusive Rocks of the, A. D. N. Bain, 214
K'unlun und Karakorum-Himalaya, Geologische Forschungen im westlichen, Dr. H. de Terra and others (*Review*), 600

$LaAl_4$, Crystalline Structure of the Compound, A. Rossi, 924
Lactic Acid, Emetic Derivatives of, Volmar and Betz, 410
Lambing Season in Great Britain, 557
Lamellibranchs, Artificial Ridges of the Valves of (Northern Annam), Mlle. M. Colani, 523
Lancaster Frankland Chemical Society, Inauguration of the, 196; Prof. H. E. Armstrong elected president, 197
Land Utilisation: Maps, 198; Survey, Second Annual Report of the, 396
Landolt's Reaction, Retarding Action of Glass on, A. Juliard, 338

Language: Difficulty and Scientific Progress, 197; in Civilization, The Spirit of, K. Vossler. Translated by O. Oeser (*Review*), 152; in the Service of Science, 741
Landslide at Toge, Japan, Prof. N. Nasu and Prof. N. Miyabe, 99
Late-Glacial Re-advance Moraines of the Highland Border West of the River Tay, J. B. Simpson, 522
Latent Image, Evolution of the, C. Jausseran, 410
Latitude, Variation: Effect in, Correlatable with the Moon, Prof. H. T. Stetson, 437; of, Dr. J. C. Dobbie, 769
Lattice Distortion, Selective, in Wires under Torsion, W. A. Wood, 842
Lead: Effects of the Addition of Tellurium to, W. Singleton and Brindley Jones, 696; from Cyrtolite, Baxter and Alter, 881; Volumetric Determination of, A. Travers and Lu, 523
Least Squares, Method of, Sir Arthur Eddington, 374
Leather, Examination of, for the Presence of Extractable Chromium Compounds, F. E. Humphreys and H. Phillips, 813
Leben und Erkennen: Vorarbeiten zu einer biologischen Philosophie, Prof. G. Wolff (*Review*), 529
Leeches, Land, Prof. J. P. Moore, 63
Leeds University: A. V. Williamson elected reader in geography, 372; gifts by C. R. Brotherton and B. Scattergood; renewal of subscription of the West Yorkshire Coal Owners' Association, 665; Report for 1931–32, 700; Dr. W. MacAdam elected professor of clinical medicine; Dr. R. H. Evans appointed lecturer in civil engineering; gift from Mrs. Graham, 772; Pathology and Bacteriology at, 835; Institution of a diploma course in biology in, 920
Legendre, Centenary of the death of, 18
Leguminous Seeds, Nutrition with, and Reproduction, V. Zagami, 108
Lepidoptera, Nomenclature in (*Review*), 566
Lepidosiren: Pelvic: Fins of the, G. E. H. Foxon, 732; Filaments of, J. T. Cunningham and D. M. Reid; G. E. H. Foxon, 913; The Pituitary in, and its Development, T. Kerr, 523
Leverhulme Research Fellowships, Appointment of an Advisory Committee, 795
Leyden Observatory, Report for 1932, 553
Libyan Desert, Volcanic Craters in the, Dr. K. S. Sandford, 46
Liesegang Rings: Dr. E. S. Hedges, 169; and other Periodic Structures, Dr. E. S. Hedges (*Review*), 316
Life and Thought: My, an Autobiography, A. Schweitzer. Translated by C. T. Campion (*Review*), 785
Light: and Life, Prof. N. Bohr, 421; 457; for Interferometer Work, Sources of, Rolt and Barrell, 244; in Interstellar Space, Absorption of, J. Dufay and Ssu-Pin Liau, 923; Measurement of, for Biological Purposes, Dr. W. H. Pearsall and P. Ullyott, 694; -Sensitive Apparatus, Practical Applications of, Major C. E. Prince, 430; -Spots, Faint Transient, Photography of, Dr. L. F. Richardson, 401
Lightning: Flash, A Destructive, Dr. C. V. Boys, 765; Investigation in South Africa, W. H. F. Tredre, 19; Progressive, A New Stereoscope, Dr. C. V. Boys, 492; Protection Against, Code for, 509
Lilydale Limestone, Stromatoporoids of the, Elizabeth A. Ripper (1), 106
Limestone Oil Wells, Reopening, with Acid, 541
Limnologie, regionalen, Grundzüge der, Prof. E. Naumann (*Review*), 223
Limpets, Age and Growth of, N. Abe, 30
Linear Partial Differential Equations in the Plane, M. Brillouin, 410
Linen Research Association, Report of the, 614
Lines of Varieties, Curvature of, T. Boggio, 71
Linnean Society of London: election of Dr. E. D. Merrill, Dr. E. Baur, Prof. A. Pascher and Prof. F. Silvestri as foreign members, 759; election of officers, 798; Linnean medal presented to Prof. R. Chodat, 798
Liquid Surfaces, Instability of, Dr. L. Rosenhead, 175
Liquids: on Solid Surfaces, Spreading of, Buckley and Snyder, 407; with Gases, Supersaturation of, T. N. Richardson and Dr. K. C. Bailey, 762
Lister Institute, Report of the, 870
Lithium Alloys, A. Baroni (1), 71
Liver and Liver Extracts, Iron and Copper in, H. G. Rees, 702
Liverpool University: bequest to, by Dr. J. M. Hunt, 51; Prof. J. Proudman elected professor of oceanography in, 391; gift to, by W. Horton, 557
Living Machinery, Prof. A. V. Hill (*Review*), 860
Local Lists of Animals, Prof. A. E. Boycott, 94
Locusts: in South Africa, The Phases of, Prof. J. C. Faure, 423; South African, Phases in, B. P. Uvarov, 423
Logarithmetica Britannica: being a Standard Table of Logarithms to Twenty Decimal Places, Dr. A. J. Thompson. Part 5: Numbers 50,000 to 60,000 (*Review*), 785
Lolium Seedlings, Fluorescence of, in Ultra-Violet Light, P. A. Linehan and Prof. S. P. Mercer, 202
London: Hospital, Collected Researches, 1932, 835; School of Hygiene and Tropical Medicine: Annual Report, 177; Hand List of Periodicals. Second edition, C. Barnard, 906; Subsidence of, T. E. Longfield, 558; University: Grants to, by City Companies, 104; Prof. L. N. G. Filon elected vice-chancellor; title of reader in experimental physiology conferred on H. P. Gilding; F. A. Greene appointed a fellow of King's College, 177; grants from the Leathersellers' Company and the Pilgrim Trust, 248; Prof. J. B. S. Haldane appointed professor of genetics at University College; W. P. Yetts appointed professor of Chinese art and archæology at the Courtauld Institute of Art; Prof. C. L. Burt appointed Heath Clark lecturer for 1933, 336; conferment of the title of reader in experimental physiology on H. P. Gilding; conferment of doctorates, 372; bequest by A. L. Leon; J. Stinton Jones appointed consultant engineer for heating etc. for the new buildings in Bloomsbury, 408; Prof. A. J. S. Pippard appointed professor of civil engineering at Imperial College—City and Guilds College; P. M. S. Blackett appointed professor of physics at Birkbeck College; W. R. Spurrell appointed reader in physiology at Guy's Hospital Medical School; Dr. Vera Anstey appointed Cassel lecturer in commerce at the London School of Economics, 480; conferment of doctorates, 628; grants by City Companies, 700; Report for 1932–33, 736; and the British Museum, 755; C. A. Mace appointed reader in psychology at Bedford College; title of reader conferred on Dr. Katharine H. Coward, Dr. D. C. Jones, and B. Topley; award of Dunn exhibitions to J. C. B. Bone and J. S. Horn, 772; title of professor conferred on Dr. L. S. Stebbing, 811; grants from City Companies, 884; and the Development of Science, 896; The New Buildings for the, T. Ll. Humberstone, 903; award of doctorates, 920
Lonicera, Presence of a Centrosomic Apparatus in Species of the Genus, P. A. Dangeard, 886
Loudness, Scales of, B. G. Churcher and A. J. King, 760
Low Temperature Research, Prof. Keesom, 768
Lubricants, Hydrogenated Motor, 643
Lubricating Oils, Volatility Range of, Measurement of, R. N. J. Saal and C. G. Verver, 661
Lucerne 'Flea', Ecology of the, D. S. Maclagan, 556
Lunar Periodicity in Reproduction, Prof. T. A. Stephenson, 622
Lund Zone of the Astronomische Gesellschaft Catalogue, Proper Motions in the, W. Gyllenberg, 245
Lyons Atmosphere, Progressive Darkening of the, A. Allix, 179

Machine Age's Starvation Predicted, Prof. R. A. Gortner, 393
Macrolepidoptera of the World: The, a Systematic Description of the Hitherto Known Macrolepidoptera. Edited by Prof. A. Seitz. Suppt. to Vol. 1: The Palæarctic Butterflies (*Review*), 566

Madagascar: Social Organisation and Marriage in, R. Linton, 843; Zoologie der, G. Grandidier et G. Petit (*Review*), 748

Maglemose in Britain, Age of, H. and M. E. Godwin, 551

Magnesium: Chlorite and Double Chlorites of Copper with Magnesium, Barium and Thallium, G. R. Levi and D. Ghiron, 775; Silicides, Thermal Decomposition of the, G. Gire, 923; Sublimation of, in a Vacuum and Casting in an Atmosphere of Argon, J. Herenguel and G. Chaudron, 179; Zinc and Aluminium Films, Structure of, Prof. G. I. Finch and A. G. Quarrell, 482

Magnetic: and Electric Double Refraction, Anomalous Dispersion in, M. Schwob, 630; Data and Mine Surveying, T. G. Bocking, 768; Disturbances, Recent, Rev. J. P. Rowland, 764; Double Refraction of Some Cerium Salts in Aqueous and Non-Aqueous Solutions, C. Haenny, 887; Measurements at Mogadiscio, M. Bossolasco, 560

Magneto-Rotation in Coloured Glass and Rock Salt, G. Kürti, 411

Malabar House, The, Dr. M. D. Raghavan, 29

Man: and Medicine: an Introduction to Medical Knowledge, Dr. H. E. Sigerist. Translated by Margaret Galt Boise (*Review*), 894; and Metals: a History of Mining in Relation to the Development of Civilisation, Dr. T. A. Rickard. 2 vols. (*Review*), 743; Ancient and Modern, Dr. S. Zuckerman, 367; Constitution and Temperament in, K. H. R. Edwards, 832; The Inequality of, and other Essays, Prof. J. B. S. Haldane (*Review*), 529; The Races of, Differentiation and Dispersal of Man, Prof. R. B. Bean (*Review*), 712

Managerial and Administrative Problems, Study Group on, 719

Manchester University: Prof. I. M. Heilbron appointed professor of organic chemistry; retirement of Dr. J. Prescott and J. Winterbottom, 772; Dr. M. Polanyi appointed professor of physical chemistry in, 902

Manihiki and Rakahanga, Cook Islands, Ethnology of, Te Rangi Hiroa (Dr. P. H. Buck), 588

Mankind, The Proper Study of, B. A. Howard (*Review*), 676

Manure, Distribution of, 445

Maps, Reproductions of Early Engraved, 2: English County Maps in the Collection of the Royal Geographical Society. With Introduction and Notes by E. Heawood (*Review*), 530

Marble, Solution of, in Acids, Velocity of, W. Jacek (3), 887

Marcapata Valley, Eastern Peru, Geology of the, J. A. Douglas, 70

'March Brown' of the Angler, The, 481

March Winds, 285

Marianas Islands, Archæology of the, Laura Maud Thompson, 623

Marine Fishes, Low Temperatures cause Mortality amongst, 373

Market Gardening, Recent Developments in, 395

Marmite, Medicinal and Dietetic Value of, 616

Marquesan Insects, I, 623

Marquis, The, and the Land Agent, Prof. G. N. Watson, 67

Marrubiine, New Method of Preparing, L. J. and F. Mercier, 143

Mars: Canals on, H. B. Brydon, 518; Planet, The Minor Details of, Dr. E. M. Antoniadi, 802; Recent Observations of, Dr. R. L. Waterfield, 845

Mathematical Association, Annual Meeting of the, 67

Matrices and Continued Fractions, Prof. H. W. Turnbull, 922

Maya and Aztec, Gods of, J. E. Thompson, 171

Mayas, Sacred Sandstone of the, Prof. T. D. A. Cockerell, 656

Mayflies and Man, 701

May Sunshine, 629

Maze, Symbolism of the, W. F. J. Knight, 98

Mechanics and Acoustics, Physical Principles of, Prof. R. W. Pohl. Translated by Winifred M. Deans (*Review*), 320

Medical: Biography (*Review*), 40; Research Council and the Rockefeller Foundation, award of travelling fellowships to H. W. Fullerton, Miss M. H. Roscoe, Dr. D. Sheehan and Dr. D. Zuckerman, 907

Medieval Faith and Fable, Rev. Canon J. A. MacCulloch (*Review*), 80

Mediterranean Region: The Geography of the, Its Relation to Ancient History, Prof. Ellen Churchill Semple (*Review*), 317

Memory, Experiments on (*Review*), 309

Mercury, Visible Triplet Lines of, Band Spectra which Appear Near, E. Matuyama, 58

Mesolithic Age in Britain, 32

Metals in very Thin Plates, Reflecting Power of, P. Rouard, 36

Metamorphism: a Study of the Transformations of Rock Masses, Dr. A. Harker (*Review*), 310; in Rocks, the Process of, Prof. P. Niggli (*Review*), 310

Meteor Craters, Prof. F. A. Melton and W. Schriever, 100

Meteoric Craters, Dr. L. J. Spencer, 172

Methylnornarcotine, Glycuronic Acid, and Vitamin C, W. J. Dann, 24

Mexico and Guatemala, Recent Discoveries in, 101

Mechanik und Akustik, Einführung in die, Prof. R. W. Pohl. Zweite Auflage (*Review*), 568

Mechanical Transport in India, Col. F. P. Barnes, 578

Mechanik, Handbuch der physikalischen und technischen. Herausgegeben von Prof. F. Auerbach und Prof. W. Hort. Band 3: Statik und Dynamik elastischer Körper nebst Anwendungsgebieten, zum Gebrauch für Ingenieure, Physiker und Mathematiker. Band 4, Hälfte 1: Lief. 1. Lief. 2. Band 4, Hälfte 2: Technische Physik der festen Körper, zum Gebrauch für Ingenieure, Physiker und Mathematiker (*Review*), 748

Medical: Education, Methods and Problems of, Vol. 21, 441; Research Council: Sir Thomas Lewis appointed a member of the, 581; Report of the, for the year 1931–1932, 753; in Great Britain, 753

Medicine: Man and, an Introduction to Medical Knowledge, Dr. H. E. Sigerist. Translated by Margaret Galt Boise (*Review*), 894

Melanogenesis, Biological Signification of, E. Friedheim, 483

Melanophore Reactions, Cellular Transmission of Neurohumoral Substances in, G. H. Parker, 776

Melchett Medal of the Institute of Fuel, award of the, to Sir John Cadman, 581

Membrane Equilibria (*Review*), 859

Mendel medal of Villanova College, award of the, to Prof. H. S. Taylor, 759

Mendelian Factors in Quantitative Inheritance, Number of, Dr. R. A. Fisher, 400

Mental Deficiency Practice: the Procedure for the Ascertainment and Disposal of the Mentally Defective, Dr. F. C. Shrubsall and Dr. A. C. Williams (*Review*), 456

Mercury: Hornsby's Observations of, 405; Arc Rectifiers, 54; Fulminate, Thermal Decomposition and Detonation of, Prof. W. E. Garner and H. R. Hailes, 286

Merget's Phenomenon, Production of, by d'Arsonvalisation with Short Waves, H. Bordier, 375

Mesopotamia, Northern, Excavations in, 685

Metallic: Neodymium Free from Iron and Silicon, Preparation of, F. Trombe, 595; Objects in Museums, Preservation of, Dr. A. Scott, 906

Metals: and Civilisation (*Review*), 743; Cold Working of, Energy absorbed in the, Rosenhain and Stott, 769; in the Service of Human Life and Industry, Sir Harold Carpenter, 733; Institute of, election of officers, 467; Journal of the, Vol. 49. Edited by G. Shaw Scott (*Review*), 187

Meteor Crater: Age of, Prof. E. Blackwelder, 404; Arizona, D. M. Barringer, 579

Meteoric Irons and Silica-Glass from the Meteorite Craters of Henbury (Central Australia) and Wabar (Arabia), Dr. L. J. Spencer, 250

Meteorite : Scars in Carolina, Probable, F. A. Melton and W. Schriever, 624 ; The Great Siberian, 614
Meteorological : Data, Correlation of, Sir Gilbert Walker, 284 ; Records of Southport, 199
Methane : Action of Steam on, C. Matignon and M. Séon, 215 ; Halogen Derivatives of, Infra-red Absorption Spectra of some, J. Lecomte, 738
Methionine in Wool, J. Barritt, 689
Methylene Blue, Reduction of, by an *Endomyces* at the expense of its Endocellular Hydrogen Donators, F. Chodat and M. Junquera, 815
Metrology by Light Waves at the National Physical Laboratory, 192
Metropolitan-Vickers Electrical Co., Ltd. : Representatives in Russia, 428 ; the Research and Testing Departments of the, 126 ; 649
Mexican and Ecuadorian Copper and Bronze Axes, M. A. Clement, 279
Mexico's "Houses of the People", 557
Mice under Continued Treatment with Œstrin, Some Effects Observed in, H. Burrows, Prof. E. C. Dodds, and N. M. Kennaway, 801
Microscope : Evolution of the, R. S. Whipple (*Review*) 219 ; The History of the, compiled from original instruments and documents, up to the introduction of the Achromatic Microscope, Dr. R. S. Clay and T. H. Court (*Review*), 219
Middlesex in British, Roman and Saxon Times, Sir Montague Sharpe. Second edition (*Review*), 677
Migration from and to Great Britain, H. Leak and T. Priday, 125
Milk : the Colloidal Calcium Phosphate of, G. T. Pyne and J. J. Ryan, 35 ; the Freezing-Point of, G. W. Monier-Williams, 702 ; Report of the Reorganisation Committee for (Ministry of Agriculture and Fisheries), 605 ; Supply, Agriculture and, Prof. H. E. Armstrong, 605
Milne's Theory of the Expansion of the Universe, Dr. G. C. McVittie, 533
Mind-Body Relation, Absurdity of any, Dr. C. S. Myers, 579
Mindouli-Mines Region, Stratigraphical Study of the, H. Lagotala, 144
Mineral Oils, Dewaxing and Acid Refining, Dr. N. O. Backlund, 31
Mineralogy : A Textbook of, with an extended treatise on Crystallography and Physical Mineralogy, Prof. E. S. Dana. Fourth edition, revised and enlarged by Prof. W. E. Ford (*Review*), 318
Miner's Nystagmus, Third Report on, 394
Mines : Roof Falls in, Prevention of, 140 ; Underground Lighting in, R. H. Campin, 465
Mining : and Metallurgy, Institution of, award of the gold medal to Sir John Cadman, 432 ; Institute of Scotland, C. A. Carlow elected president of the, 650
Minnesota Pleistocene *Homo*, A. E. Jenks, 739
Mistral, Greatest Strength of the, 338
Mites of Fruit Trees, A. M. Massee, 136
Mitochondria, Fixation of, J. H. Davie, 59
Mitogenetische Strahling, Die, zugleich zweiter Band der "Probleme der Zellteilung", Prof. A. Gurwitsch. Unter Mitwirkung von Lydia Gurwitsch (*Review*), 79
Mixtures of Substances of Large Electric Moment, Magnetic Susceptibility of some, J. E. Garssen, 523
Molecules : of Intermediate Complexity, Kinetics of the Decomposition of, C. N. Hinshelwood and C. J. M. Fletcher, 24 ; Simple, and Elementary Processes, Prof. A. J. Allmand, 173
Mole's Winter Store of Earthworms, 285
Mollusca, The British Marine, R. Winckworth, 334
Molybdenum, Distribution of, Dr. W. A. Roach, 202
Monte Rosso di Verra, Mineral Deposits of, T. Carpanese, 775 ; (2), 924
Moon : New, An Early Observation of the, 100 ; Partial Eclipse of the, Sept. 14, 1932, Photometric Study of the, F. Link, 179
Moon's Shadow on the Earth, Photographing the, W. M. Browne, 697
Mornington Earth Tremor of Sept. 3, 1932, W. M. Holmes, 71
Motor Car Lights on the Road, Dr. Dickinson, 20
Mousterian Age, A Spear-Point of Bone of, Abbé Breuil, Dr. H. Martin, 53
Mole, Captive, Observations on a, L. E. Adams, 466
Mollusca, Spawning in, Spring Outburst of, 445
Morphology, The Old, and the New, Dr. H. Hamshaw Thomas, 47
Mother-Tongue in India, Use of the, 444
Mottramite and Psittacinite, Identity of, with Cupriferous Descloizite (Cuprod-Escloizite), F. A. Bannister, with chemical analyses by M. H. Hey, 250
Mucor, Biometric Researches on the Spores of, W. Schopfer, 483
Murray, John, Expedition, The, Prof. J. Stanley Gardiner, 640
Muscular Work, Fatigue and Recovery, G. P. Crowden (*Review*), 321
Museums : of British Territory and the Mediterranean, 430 ; of Canada, 84
Musk : -Rat in Britain, The, Prof. J. Ritchie, 385 ; -Rats at the London Zoo, 755
Mussel, Strange Spatfall of the Common, on the Common Cockle, Prof. J. H. Orton, 513
Mutations, Spontaneous, Origin of, M. Navashin, 436
Mutsu Bay, Tintinnids of, 695
Mycorrhiza on Conifer Roots, 176
Mycorrhizal Theory, Objections to the, J. Costantin, 447

Nationalism and Academic Freedom, 853
National : Physical Laboratory, Collated Researches of the. Vol. 23, 162 ; New Radio Department of the, R. A. Watson Watt appointed superintendent, 720
Native Reserves, Gold in Kenya and, 37
Natural History : Intensive, Prof. E. J. Salisbury (*Review*), 343 ; The Standard, from Amœba to Man, G. J. Arrow and others. Edited by W. P. Pycraft (*Review*), 152
Naturalist, resignation of T. Sheppard of editorship of the, 304 ; The, and the Country Side (*Review*), 636
Naturwissenschaften, Die (birthday of Dr. Arnold Berliner), 127
Natuna Islands, Birds of the, H. C. Oberholser, 207
Naturæ, Vox, E. Terbea (*Review*), 491
Naval Architects, Institution of : award of premium to Dr. G. Kempf and H. Lerbs, 164 ; Lord Stonehaven nominated as president of the, 432
Navy, Health of the, 1931, Vice-Adm. R. St. G. S. Bond, 906
Nebulosity Surrounding a Nova, Illumination of, B. M. Peck, 808
Nematodes, Parasitic, Cultivation of, G. Lapage, 583
Neodymium-Samarium Fractionation, Radioactivity of a, M. Curie and S. Takvorian, 702
Neolithic Fortress, Late, Homolka, Bohemia, V. J. Fewkes, 207
Neon Discharge Tubes, Behaviour of, in a Flashing Capacity Circuit by Means of a Cathode Ray Oscillograph, J. H. J. Poole, 35
Neoteny and Pædogenesis, Meaning of, G. E. H. Foxon, 93
Nerve : Action of Quaternary Ammonium Salts on, S. L. Cowan, 658 ; Impulse, Nature of the, Prof. A. V. Hill, 233 ; 497 ; 501 ; Mitogenetic Radiation of, Dr. A. Gurwitsch, 912
Nesting Season, Opening of the, 445
Nettle, Stinging, Eradication of the, G. H. Bates, 208
Neural Energy Constant : The, A Study of the Bases of Consciousness, Dr. J. Bostock (*Review*), 80
Neuro : Humoral Mechanisms, Prof. R. J. Brocklehurst, 65 ; -Muscular Junction, the, and Curare, Tudor Jones, 693
Neuton, The Neutron and, The New Element of Atomic Number Zero, Prof. W. D. Harkins, 23
Neutral Aryl Sulphites, Reaction of Phosphorus Pentachloride on the, P. Carré and D. Libermann, 667

Neutron: and Neuton, The, The New Element of Atomic Number Zero, Prof. W. D. Harkins, 23; and Proton, Law of Force between, E. C. Pollard, 814; Chemical Nature of the, P. Achalme, 559; Proton, and Positron, Dr. N. Thon, 878; The, Dr. J. Chadwick (Bakerian lecture), 794

Neutrons: Dr. D. Meksyn, 366; Conditions of Emission of, by the Action of α-Particles on the Light Elements, Mme. Irène Curie and F. Joliot, 447; Emission of, by Aluminium under the Action of the α-Particles, P. Auger and G. M. Herzen, 523

New Britain, 358

Newfoundland: Fishery Research in, 918; Ice off, 409

New South Wales: Association of the Tertiary Alkaline Rocks of, with late Tertiary Tectonic Lines, C. A. Sussmilch, 667; Linnean Society of, Prof. A. N. St. G. H. Burkitt elected president of the, 759; Mineralogy of the Narrabeen Series of, Alma G. Culey, 523

New Year Honours, 17

New Zealand, Trout Fishing in, Prof. E. Percival, 163

Niari: Limestones of, Continental Formation Subjacent to the, H. Lagotala, 851; Stratigraphic Scale of the, H. Lagotala, 215

Nickel: and Nickel-Chromium Alloys in the Neighbourhood of their Curie Points, Measurements of the Thermoelectric Powers of, A. W. Foster, 814; Salts, Electrolysis of, Influence of the Magnetic Field on the, H. Forestier, 70

Nicotine, the Toxic Action and Elimination of, N. Sabatucci (1–2), 483

Niger, Barrages on the, 466

Nigeria, Census of, S. M. Jacob, 516

Nile Flood, 921

Niobium, Determination of, by Orthoxyquinoline, P. Süe, 738

Nitrates in the Soil, Distribution of, and Root Development in Coffee, V. A. Beckley and F. McNaughtan, 878

Nitrobenzene, Debye's Dispersion of, Prof. R. Weigle and R. Luthi, 327

Nitrogen: Dioxide, Infra-Red Absorption Spectrum of, C. R. Bailey and A. B. D. Cassie, 239; Dioxide Molecule, Form and Vibrational Frequencies of the, C. R. Bailey and A. B. D. Cassie; R. Schaffert, 910; Fixation in the Genus *Lolium*, R. Brown, 169; Organic, Estimation of, in the presence of Nitrates by Kjeldahl's Method, R. Cambier and L. Leroux, 179; -Uptake of Plants, Prof. A. I. Virtanen, 534

Nitrogenous Manuring of Legumes, H. Burgevin, 660

Nitrous Oxide: and Carbon Dioxide, A Bomb Calorimeter Determination of the Heats of Formation of, R. W. Fenning and F. T. Cotton, 446; in the Glow Discharge, Dissociation of, E. A. Stewardson, 364

NO_2: Extension of the Visible Absorption System of, to longer Wave-lengths, J. Curry and Dr. G. Herzberg, 842; Molecule, Form and Vibrational Frequencies of the, Dr. L. Harris, W. S. Benedict and G. W. King, 621

Nomogram: The, The Theory and Practical Construction of Computation Charts, H. J. Allcock and J. R. Jones (*Review*), 785

Non-Linear Equations of the Elliptic Type, G. Giraud, 215

North: Atlantic Gale, 18; China Amphibia and Reptiles, Handbook of, Dr. Alice M. Boring, C. C. Liu, and S. C. Chou, 304

Northern Lights: The Official Account of the British Arctic Air-Route Expedition, 1930–1931, F. S. Chapman, and others (*Review*), 317

Norton, Thomas, and the "Ordinall of Alchimy", Dr. E. J. Holmyard, 520

Norwegian: Antarctic Expedition, Capt. H. Riiser-Larsen, 301; Oyster Pools, T. Gaarder and R. Spärck, 806

Nova: A Remarkable Short-Lived, Delporte and Arend, 553; of March 20, Dr. Kukarkin, 590; Phenomenon, Frequency of the, C. Lönnqvist, 64

Nuclear: Potential Barriers, Heights of, E. C. Pollard, 97; α-Particles, Fundamental State of, Dr. G. Gamow, 618; Energy Levels, Dr. G. Gamow, 433; Moments, Predictions of, Prof. B. Venkatesachar and T. S. Subbaraya, 552; Potential Barriers, Heights of, and Nuclear Structure, E. C. Pollard, 398

Nucleic Acids and Uracil, Irradiation of, F. F. Heyroth and J. R. Loofbourow, 92

Numerical Coincidence, A, H. P. Hollis, 550

Nutrient Salts in the Sea, Depletion of, 445

Nutrition, Recent Investigations in, 357

Oaks in Cultivation in the British Isles, Sir Oscar and E. F. Warburg, 905

Oats, Grain Colour in, Inheritance of, W. Robb, 517

Observer's Handbook for 1933, 369

Obstacles Revolving Round an Axis Parallel to the General Direction of Flow, Vortices Produced by, P. Dupin and M. Teissié, 179

Oceanographical Work of the *Carnegie* (*Review*), 114

Oceanography: (Bulletin of the National Research Council. No. 85: Physics of the Earth, 5) (*Review*), 344; Progress of, 214

Octopus vulgaris, Hæmocyanin of, Svedberg and Erikson, 137

Œnothera, Phylogeny in the Genus, Prof. R. R. Gates, 589

Œstrogenic Substance from Plant Material, An, Dr. B. Skarżyński, 766

Œstrus-exciting Compound, A Synthetic, Dr. J. W. Cook, Prof. E. C. Dodds, and C. L. Hewett, 56

Oil: and Natural Gas, Migration of, Prof. V. C. Illing, 475; and Water, Separation of, Molecular Phenomena at the Surface of, J. J. Trillat and L. Leprince-Ringuet, 850; Oxidation and the Lubricating Properties of, R. O. King, 476; Reserves and Production, V. R. Garfias, 868; Seeds and Vegetable Oils, Survey of, Vol. 2, 542

Oldoway Human Skeleton, The, Dr. L. S. B. Leakey, Prof. H. Reck, Prof. P. G. H. Boswell, A. T. Hopwood, and Dr. J. D. Solomon, 397

Old: Trades and New Knowledge, Sir William Bragg (*Review*), 860; Wine and New Bottles, Dr. A. Ferguson (*Review*), 417

Olefinic Compounds, Catalytic Hydrogenation of, Dr. E. H. Farmer and R. A. E. Galley, 60

Olive, A Non-Parasitic Alteration of the, R. Gigante, 851

Omaha Secret Societies, Dr. R. F. Fortune, 331

Opiliones-Laniatores, The Arachnid Group, late Dr. W. Sørensen, revised by Dr. C. With and Dr. K. L. Henriksen, 543

Ophiocytium Nageli in Victoria, Two Species of, *O. terrestris* n.s. and *O. arbuscula* Rabenhorst, Jean Heyward, 107

Opium Poppy, Atavism in a Strain of the, L. Blaringhem, 178

Optic Tectum, A Phylogenetic Consideration of the, G. K. Huber and Elizabeth C. Crosby, 739

Optical: Rotatory Power, Prof. T. M. Lowry and H. Hudson (4), 374; Rotatory Power, Fundamental Laws of, Prof. W. Kuhn, 771

Ordovician Rocks of the Trefriw District, North Wales, D. A. Bryn Davies, 595

Organic: Reagents for Metals, Hopkin and Williams, Ltd., 396; Oxides, Dissociable, C. Dufraisse and J. A. Monier, Jr., 887; Syntheses: an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. F. C. Whitmore, editor-in-chief. Vol. 12 (*Review*), 604

Orthogonal Polynomials with Two Variables, M. Ghermanesco, 107

Orthophosphoric Acid, Action of Solutions of, on Ordinary Cellulose, G. Champetier, 703

Orthopodomyia pulchripalpis, Rondani (*Diptera, Culicidæ*), A New British Record of, J. F. Marshall and J. Staley, 435

Osiris and the Atom, J. G. Crowther (*Review*), 320

Osler and other Papers, Prof. W. S. Thayer (*Review*), 40

Outline Series, The. 11 vols. (*Review*), 8

Ovaries, Transplantation of, Preserved Outside the Organism, A. Lipschütz, 143
Ovulation Without 'Heat' in the Ewe, Occurrence of, R. Grant, 802
Oxford University: Dr. G. D. Hale Carpenter appointed Hope professor of zoology, 159; Junior Scientific Club, Jubilee of the, 757; Old Ashmolean, 250th Anniversary of the, 684; Report of the Lewis Evans Collection, 884
Oxide Catalysts, Positive Ion Emission from, Dr. C. F. Powell and Luang Brata, 168
Oxides, Dissociable Organic, C. Dufraisse and R. Buret, 70
Oximes and Semicarbazones, Colour and Structure of, Mme. Ramart-Lucas and Mme. M. Grumez, 70
Oxyflavonic Compounds, Microchemical Characters of the, A. Guilliermond and R. Gautheret, 410
Oxygen: Commercial, Manufacture of, G. Claude, 70; Hydrogen and, Reaction between, C. N. Hinshelwood, E. A. Moelwyn-Hughes and S. C. Rolfe, 625; Liquid, Magnetic Double Refraction of, P. Lainé, 850; Molecule, Magnetic Behaviour of the, R. Einaudi, 71
Oxyquinoline, Azo Derivatives of, Utilisation of Some, as Reagents in Qualitative Analysis, G. Gutzeit and R. Monnier, 144
Oysters (*O. edulis*), Breeding of, at Port Erin, Prof. J. H. Orton, Miss M. W. Parke and W. C. Smith, 26
Ozone: Liquid, Magnetic Properties of, P. Lainé, 702; Photosensitised Decomposition of, by Chlorine, Dr. R. G. W. Norrish and G. H. J. Neville, 544

Pacific: Influence of the, on the Circulation in the South-West Atlantic Ocean, A. J. Clowes, 189; Islands, Reptiles and Amphibians of the, C. E. and May Danheim Burt, 767; Ocean, Soviet Expedition to the, 391; Science Congress, Fifth, 757; Scientific Problems of the, Lord Rutherford, 831
Pædogenesis, Neoteny and, Meaning of, G. E. H. Foxon, 93
Paint and Varnish Industries, Research in the, 794
Painted Lady Migrates, The, 849
Palæontographical Society, election of officers, 649
Palæozoic: Fossils from Victoria, F. Chapman, 703; Planktonic Faunas of North America, R. Ruedemann, 775
Palestine: Ancient Man in, Miss Dorothy Garrod, 19; M. T. Dawe appointed director of agriculture and forests, 543; Mesolithic Culture in, 767
Pamir, A Photogrammetric Survey in the, P. Lake (*Review*), 744
Panda, The, at the Zoological Gardens, 428
Papal Observatory in Castel Gandolfo, 124
Papua, Depopulation in, Sir Hubert Murray, and others, 519
Paraffins, Normal, Crystal Structure of the, Dr. A. Müller, 100
Paramagnetic Susceptibility, Influence of Light on, P. W. Selwood, 761
Parc National Suisse, Les Insectes Forestiers du, Dr. A. Barbey, 234
Paris Academy of Sciences, Prize awards of the, 174
Parsons: Charles, his Life and Work, R. Appleyard (*Review*), 891
Particle Size and X-Ray Spectroscopy, Fonda, 332
Partridge Disease, 177; and its Causes. Edited by Major M. Portal and Dr. W. E. Collinge (*Review*), 224; Numbers, Fluctuations of, 178; Shooting, 142
Passivity Phenomena, Theory of, W. J. Müller (18), 888
Pasteur, Louis, The Genius of, P. Compton (*Review*), 40
Pastures, Nutritive Value of, E. J. Sheehy, 30
Patents: British, and Designs Statutes as Amended and Consolidated to 1932. With an Introduction and Index by H. J. W. Bliss (*Review*), 79; for Chemists, The Law of, Dr. J. Rossman (*Review*), 115; Trade Marks and Designs: their Commercial Aspect and Development, C. W. Thomas (*Review*), 79
Patwin and Maidu Cult Origins, E. M. Loeb, 659
Pearl Oysters, Breeding of, coincident with Full Moon, 665
Pedigree Schedules: the Study and Preparation of Family Records (*Review*), 712
Peirce, Charles Sanders, Collected Papers of. Edited by C. Hartshorne and P. Weiss. 2 vols. (*Review*), 639
Pelagic Organisms, Unusual Occurrence of, Prof. W. J. Dakin, 239; G. P. Farran, 240
Penetrating Radiation, Photography of the Tracks of, P. M. S. Blackett and G. Occhialini, 286
Penguin Embryos, C. W. Parsons, 695
Pepys, Samuel: Christ's Hospital and, 267; Tercentenary: of, T. E. James, 228; and the Royal Society, 299; E. Chappell, 833; The Priestley and, Commemorations, 443
Periodic: Functions, Almost, A. S. Besicovitch (*Review*), 384; Light Beam, Action of a, on Metallic Sheets, Q. Majorana, 447
Permanganate, Action of Hydrogen Peroxide on, P. Dubois, 923
Persepolis, Excavations of, 233
Persia, "Wind of 120 Days", 773
Perturbed Series, Hyperfine Structure of, E. Gwynne Jones, 813
Peterhead Sealers and Whalers, Dr. R. W. Gray, 904
Petrography and Petrology: a Textbook, Prof. F. F. Grout (*Review*), 317
Pétrole, Le, de Mésopotamie et son Pipe-Line, V. Forbin, 864
Pétroles naturels et artificiels, J.-J. Chartrou (*Review*), 455
Petroleum: Congress, World, 758; Herrings and the Origin of, 578; Iraq, and Pipe-Line, 864; Production in Russia, P. C. Beckstrom, 541; Technology: and Chemical Industry, 145; Aircraft in Relation to, 160
Petrols, Vapours of, Accidental Ignition of, by Electric Sparks, A. Kling and A. Soulier, 106
Pflanzenanalyse, Handbuch der, Herausgegeben von G. Klein. Band 2: Spezielle Analyse. Teil 1: Anorganische Stoffe; Organische Stoffe, 1 (*Review*), 8
Phæocystis and Herrings, 737
Pharmacognosy, A Textbook of, J. W. Cooper and T. C. Denston (*Review*), 419
Pharmacopœia: The British, 1932 (*Review*), 6; The Extra, of Martindale and Westcott. Revised by Dr. W. H. Martindale. Twentieth edition. In 2 vols. Vol. 1 (*Review*), 6
Pharmacy, Principles of, H. B. Mackie (*Review*), 895
Phase, Variations of, by Reflection on very Thin Metallic Films, P. Rouard, 410
Phaseolus multiflorus, Petaloid Formation of the Calyx in, E. Tschermak, 560
Phenols and Naphthols, Action of Gaseous Cyanogen on, (2), G. Machek, 851; (3), 852
Phenomenal Regression to the Real Object, Dr. R. H. Thouless, 261
Philips Sodium Lamp, 440
Philosophy: Biology and (*Review*), 529; of a Scientific Man, The, P. R. Heyl (*Review*), 491
Philyrea latifolia, The Heterosides of, Mlle. A. Kramer, 631
Phlogiston Theory, The History of the, Dr. J. H. White (*Review*), 531
Phosphorescent Zinc Sulphide, Connexion between the Two General Methods for the Preparation of, R. Coustal, 887
Phosphoric Anhydride, Modifications of, K. Boratynski and A. Nowakowski, 595
Phosphorus: Liquid, Dielectric Constant of, S. Dobinski, 447; Pentachloride, Mechanism of the Reaction of, on Neutral Alkyl Sulphites, P. Carré and D. Libermann, 143; Ultra-Violet Bands of Oxide of, Prof. P. N. Ghosh and A. K. Sen Gupta, 841
12-Phosphotungstic Acid, Molecule of, Structure of the, J. F. Keggin, 908
Photocells: and their Application, Dr. V. K. Zworykin and Dr. E. D. Wilson. Second edition (*Review*), 860; of the Dry Rectifier Type for the Measurement of Daylight, Suitability of, Drs. H. H. Poole and W. R. G. Atkins, 850

Photochemical Kinetics, R. Wegscheider, 287
Photoelectric: Experiment, A New, Q. Majorana, 71; 107; Phenomenon, A New, Exhibited by Metallic Sheets, Q. Majorana, 559; Polarimeter, Improvement of the, G. Bruhat and A. Guinier, 630
Photographic: Densities, Exact Measurement of, P. Fleury and G. A. Boutry, 738; Sensibility, Influence of Pressure on the, to Various Monochromatic Radiations, Ny Tsi-Ze and Chien Ling-Chao, 286; Sensitisers for the Infra-Red, Miss N. I. Fisher and Miss F. M. Hamer, 475
Photography, Scientific and Applied, International Congress of, 212
Photometry, Everyday, with Photoelectric Cells, Dr. J. W. T. Walsh, 660
Photovoltaic Elements, Differentiation of the Electronic Effects and the Photoelectric Effects in, R. Audubert, 482
Physic, Modern (*Review*), 6
Physical: Atomic Weights, Dr. F. W. Aston, 172; Bibliographies, 615; Society: election of officers, 510; presentation of the Duddell medal to Prof. W. Gaede, 901; Society's Exhibition, Lectures at the, 66; World in Cinematography, Image of the, Torahiko Terada, 358
Physics: Elementary, G. Stead. Fourth edition (*Review*), 748; in the Boot and Shoe Industry, H. Bradley, 756; Institute of: award of prizes to E. Lancaster-Jones, Dr. J. L. Miller and J. E. L. Robinson, 467; election of officers, 797; Intermediate, Dr. C. J. Smith (*Review*), 532; Numerical Examples in, Dr. W. N. Bond (*Review*), 320; Practical, W. R. Bower and Prof. J. Satterly. Third edition (*Review*), 491; Theoretical, A Concise (*Review*), 221; The Method of, Prof. A. Einstein (Herbert Spencer Lecture), 867
Physik: ein Lehrbuch für Studierende an den Universitäten und technischen Hochschulen, Prof. W. H. Westphal. Dritte Auflage (*Review*), 895; Kosmischen, Ergebnisse der. Herausgegeben von V. Conrad und L. Weickmann. Band 1 (*Review*), 785; theoretischen, Lehrbuch der, Prof. G. Joos (*Review*), 221
Physikalisch-chemisches Taschenbuch. Herausgegeben von C. Drucker und E. Proskauer. 2 Band (*Review*), 676
Phytophthora megasperma causing Pink Rot of the Potato, H. Cairns and A. E. Muskett, 277
Phytosterol Group, Investigations in the, (2), C. Antoniani, 483
Phytosteryl Acetate Test as a Routine Method for Examining Butter Fats, H. Hawley, 814
Piedmontite in Quartz-Muscovite-Schist from the Shotover Valley, Western Otago, New Zealand, F. J. Turner, 630
Pilot Balloon Observations at Mauritius, R. A. Watson and N. R. McCurdy, 626
Piltdown Skull, A Second, Sir Arthur Smith Woodward, 242
Pinastric Acid, Constitution of, G. Koller and G. Pfeiffer, 411
Pitchblende at Great Bear Lake, Canada, H. S. Spence, 208
Pit-Head Baths, J. H. Mitchell, 207
Pituitary Gland, Action of Proteolytic Enzymes on the Oxytocic Principle of the, Dr. J. M. Gulland and T. F. Macrae, 470
Place Names, Spelling of, 161
Plane Algebraic Curves, Prof. H. Hilton. Second edition (*Review*), 383
Planet: New Minor, 808; The New, 1933 HH, 881
Planetary System, Origin of the, Dr. R. Gunn, 405
Planets: Minor, 441; Spectra of the, Prof. W. M. Slipher (George Darwin Lecture), 734
Planktonic Diatoms, Spring Increase of, 285
Plant: Genetics, Recent Advances in, Dr. F. W. Sansome and J. Philp (*Review*), 185; Histology, Methods in, Prof. C. J. Chamberlain. Fifth edition (*Review*), 44; Virus: Protective Inoculation against a, Dr. R. N. Salaman, 468; Research, Dr. Kenneth N. Smith, 915
Plants: Green, Distribution of Nitrates and 'Organisation' of Nitrogen in the Leaves of, E. Parisi and G. De Vito, 107; The Growth Hormone of, K. V. Thimann and J. Bonner, (2), 631; Physiology of, Functions of Radiation in the, F. S. Brackett and E. S. Johnstone, 331; Sexuality in, Discovery of, Dr. C. Zirkle, 392
Plastic: Materials, Exhibition of, 510; Sediments, Relative Impermeability of the, towards Rain Water, Spring Water and various Alkaline Solutions, P. Urbain, 739
Plasticine Edible ?, Is, D. I. Clements, N. H. Howes and G. P. Wells, 330
Plasticity: a Mechanics of the Plastic State of Matter, Dr. A. Nádai, assisted by A. M. Wahl (*Review*), 383
Platinum: Compounds, Decomposition of Some Complex, at Progressively Increasing Temperatures, P. Vallet, 143; Thin Spluttered Films of, Crystalline State of, Prof. G. P. Thomson, N. Stuart and C. A. Murison, 522
Pliny's Chemical Knowledge, Dr. E. J. Holmyard (*Review*), 305
Polarisationsebene des Lichtes, Drehung der, W. Kuhn und K. Freudenberg (*Review*), 677
Polarografo: Il, sua teoria e applicazioni, Dr. G. Semerano (*Review*), 260
Polar Year, International Commission for the, 1932–33, 810
Police, Technical Training of the, 754
Polish Guide to Zoology, 905
Pollination in Orchards, G. F. Wilson, 659
Polonium Acetylacetonate, Existence of a, Servigne, 375
Polynesia, Ceremonial Exchange in, Dr. I. Hogbin, 439
Population: Density and Egg-Laying in Flies, Prof. R. Pearl; Dr. Alpatov, 176; Problems in the Pacific, 519
Port: Erin Biological Station, Research at the, 21; Sanitary Regulations, Revised, 616
Positive Electron, New Evidence for the, Dr. J. Chadwick, P. M. S. Blackett and G. Occhialini, 473
Positron, Neutron, Proton and, Dr. N. Thon, 878
Potassium, Radioactive Half-Period of: Calcium Isotope with Mass 41 and the, Prof. J. Kendall, W. W. Smith and T. Tait, 688
Potato, Degenerescence in the, Variations in the Virulence of, J. Costantin, 850
Potatoes: Early, 886; in the Fens, 594; Insect Transmission of Virus *A* of, J. B. Loughnane, 838; Normal and Leaf-Roll Variations in the Total Nitrogen Content of, G. Cockerham, 375
Poultry Manure, Production of Kiln-dried, R. Sayce and F. Hanley, 198
Power: Alcohol, 341; Station Efficiency, W. S. Burge, 518
Prehistoric Society of East Anglia: Annual Business Meeting, Dr. Cyril Fox elected president for 1933, 520; *Proceedings* of the, vol. 7, pt. 1, 465
Pressures, Variable, Methods of Measuring and Recording Rapidly, A. Labarthe and M. Demontvignier, 179
Prickly Pear in Australia, Eradication of, 613
Priestley: and Pepys Commemorations, The, 443; as a Practical Chemist, Prof. T. S. Patterson, 690; Dr. A. N. Meldrum, 801; as a Scientific Man and Theorist, Sir Philip Hartog, 555; Bicentenary Celebrations at Warrington, 498; Celebration at the Chemical Society, 555; The "Leeds Portrait" of, W. C. Walker, 876; The Scientific Work of, Prof. J. R. Partington, 348
Priestley's: Associations with London, H. G. Wayling, 350; Science to Chemistry, Sir Harold Hartley, 555; Work on Gases and Nitrogen Peroxide, Prof. A. N. Meldrum, 555
Primes and Factors, Emma Gifford (*Review*), 785
Professions, The, Prof. A. M. Carr-Saunders and P. A. Wilson (*Review*), 863
Progress and Scientific Method, 1
Prosperity, The Means to, J. M. Keynes (*Review*), 451

Protein : Foods in Growth, Comparative Value of Various, E. F. Terroine and Mlle. Simone Valla, 375 ; Synthesis of, by Green Plants, L. Loose and Dr. W. H. Pearsall, 362
Proton, Neutron, and Positron, Dr. N. Thon, 878
Protons : Liberated by Neutrons, Photographic Detection of, Marietta Blau and Hertha Wambacher (2), 287 ; Produced in the Artificial Disintegration of the Nitrogen Nucleus, E. C. Pollard, 482
Protoselenosulphochloride, A. Baroni, 483
Prout's Hypothesis, Papers by Dr. W. Prout (1815–16), J. S. Stas (1860) and C. Marignac (1860) (*Review*), 152
Proverbes et maximes Peuls et Toucouleurs traduits, expliqués et annotés, H. Gaden (*Review*), 347
Psychoanalysis, The Medical Value of, Dr. F. Alexander (*Review*), 532
Psychologique, L'Année, Publiée par Prof. H. Piéron. Année 32 (1931). Vols. 1 and 2 (*Review*), 604
Psychology : Genetic, (1), J. L. Gray and Pearl Moshinsky, 922 ; in Autobiography, A History of, Vol. 2. B. Bourdon, and others (*Review*), 321
Psychotherapy, Analytical, An Introduction to, Dr. T. A. Ross (*Review*), 639
Public Analysts, Society of, election of officers, 359
Puccinia Helianthi Schw., Union of Pycniospores and Haploid Hyphæ in, J. H. Craigie, 25
Pumping Machinery, Science Museum Handbook of, G. F. Westcott, 542
Pycnogonid, A Dodecapodous, Dr. W. T. Calman, 242
Pyridine-Iodine Molecular Association, A. M. Chatelet, 923
Pyrométrie optique, Traité de, Prof. G. Ribaud (*Review*), 151
Pyrophosphoric Acid, Absorptive Power of Soil for, A. Fabris, 775
Pyrrhotite, Iron Lattice of, Vacant Positions in the, Prof. G. Hägg, 168
Pyrrolic Aldehydes, Action of Alkaline Hypoiodites on the, P. Pratesi, 924

Quail, Changed Standing of the, 337
Quantenmechanik, Die Gruppentheoretische Methode in der, Prof. B. L. van der Waerden (*Review*), 531
Quantification, Théorie de la, dans la nouvelle mécanique, Prof. L. de Broglie (*Review*), 639
Quartz : as a Standard for Accurate Lattice-Spacing Measurements, A. J. Bradley and A. H. Jay, 813 ; Crystal, Oscillating, as an Accurate Clock, Scheibe and Adelsberger, 281
Quinine Salts, Rotatory Power of, in Aqueous Solution, C. Lapp, 703
Queen : of Bermuda, Electrical Equipment of the, 796 ; of the Sciences, The, Prof. E. T. Bell (*Review*), 319
Quekett Microscopical Club, election of officers, 272

Rabbit : Blood Group Inheritance in the, W. E. Castle and C. E. Keeler, 775 ; Tests for Linkage between the Blood-Group Genes and other known Genes of the, W. E. Castle and C. E. Keeler, 775
Racial Distributions in Palæolithic Europe, M. C. Burkitt, 540
Radiation, Penetrating : Absorption of, Prof. E. Regener, 880 ; Spectrum and Latitude Variation of, Dr. E. J. Williams, 511
Radioactive : Minerals, Primary, Analysis of, A. Karl, 143 ; Substances, New, A. Debierne, 630
Radio : Communications by very Short Electric Waves, Marchese Marconi, 292 ; Direction-Finding, C. E. Horton and C. Crampton ; J. F. Coales, 846 ; -Electric Waves, Short, Apparent Velocity of, N. Stoyko and R. Jouast, 887 ; Research Board, Report of the, for the year 1931, 156 ; Telephone Links, 731 ; Union, International Scientific, Prof. A. E. Kennelly elected president of the, 55 ; Valve, The 'Catkin', 735 ; -Waves, Interaction between, B. D. A. Tellegen, 840
Radiometer Action and the Pressure of Radiation, Mary Bell and S. E. Green, 374
Radium in Canada, Assays of, H. S. Spencer, 55
Railway Electrification Experience, Col. C. Leigh, 649
Railways in Britain, Electrification of, F. Lydall, 19
Rainfall : at Capodimonte during 1833–1931, E. Guerrieri, 107 ; over the British Isles, 1820 to 1929, J. Glasspoole, 737
Raman : Effect (24), H. Kopper and A. Pongratz, 251 ; Spectra and Chemistry, 263
Rangoon, Geology and Underground Water of, P. Leicester, 916
Rare Earth : Elements, Radioactivity of some, Libby and Latimer, 368 ; Group, Use of Non-Aqueous Solvents in the Study of the, B. S. Hopkins and L. L. Quill, 739 ; Earths, Fluorescence of Pure Salts of the, Prof. R. Tomaschek and O. Deutschbein, 473
Rat : Crested, at the London Zoo, 794 ; The Crustacean Chromatophore Activator and the Gonads of the, B. Kropp, 631
Ray Society, election of officers, 466
Rayon Industry, The (*Review*), 454
Rays Entering the Eye Pupil at Different Points, Luminous Efficiency of, W. S. Stiles and B. H. Crawford, 250
Reading University : appointment of Dr. R. H. Stoughton as professor of horticulture, 248 ; Prof. R. Rae appointed professor of agriculture, 772
Recrystallisation and Coloration, Prof. K. Przibram, (3), 560
Rectifier Photo-Cells, Reversal of Current in, J. Guild, 327 ; Dr. H. H. Poole and Dr. W. R. G. Atkins, 547
'Red Coal', Prince Ginori Conti, 679
Red Deer Shed their Antlers, 629
Reflexology (*Review*), 675
Regression, Phenomenal, to the Real Object, Prof. W. Peddie ; Dr. R. H. Thouless, 544
Regulus, Occultation of, on April 6, 553
Reinmuth Planet, 1932 *HA*, Dr. G. Stracke, 369
Religious Experience : its Nature, Types and Validity, Rev. A. C. Bouquet (*Review*), 677
Relativity : Addresses and Discussions on, 722 ; and the Structure of the Universe (*Review*), 637 ; of Time, Kennedy and Thorndike, 136 ; Special Theory of, Momentum and Energy in the, Prof. A. C. Banerji, 517
Remembering : a Study in Experimental and Social Psychology, Prof. F. C. Bartlett (*Review*), 309
Renéville (French Congo), Borings in the Marly Limestones of, H. Lagotala, 215
Reproduction, Lunar Periodicity in, Prof. T. A. Stephenson, 622
Research : Financing, 289 ; in Central Asia, 705 ; The Spirit of, Dr. T. Brailsford Robertson. Edited by Jane W. Robertson (*Review*), 111
Resonance : Ag I Lines, Fine Structure of the, W. E. Williams and A. Middleton, 692 ; Radiation : Frequency Distribution of, R. W. Ditchburn, 106 ; Possibility of Separating Isotopes by the Use of, R. W. Ditchburn, 106 ; through a Gas Transmission of, R. W. Ditchburn, 738
Rhenium : Dr. E. S. Kronman (*Review*), 224 ; Metallic, The Constant Paramagnetism of, N. Perakis and L. Capatos, 559 ; Spectra of, H. Schober, (3), 411 ; (4), 851
Rhesus Monkey, Sexual Cycle in the, Dr. C. G. Hartmann, 626
Rhodesia, Southern, Meteorology in, 54
Ribaucour's Transformation and Spherical Representation (3), H. Hamburger, 339
Rice Grass, The Economic Possibilities of, J. Bryce, 368
Richborough, Roman, Dr. J. P. Bushe-Fox, 539
Rickets, Experimental, as a Phosphorus Deficiency Disease, Prof. H. D. Kay and Dr. B. L. Guyatt, 468
Ringworm Fungi, Development of Fuseaux, Aleuriospores, and Spirals on detached Hairs infected by, Dr. A. M. Davidson and Dr. P. H. Gregory, 836

Road: Island Refuges, Guard Posts for, 394; Research Board, Major F. C. Cook appointed chairman of the, 686; Station, Harmondsworth transferred to the Department of Scientific and Industrial Research, 686
Rock: -Salt, Blue, Recrystallisation and, Prof. K. Przibram, 287; Specimens of, for Measuring their Electrical Resistance, Methods for putting in Circuit, Mme. F. Bayard-Duclaux, 887
Rocks: Certain Igneous, Magnetic Properties of, A. F. Hallimond and E. F. Herroun, 338; Thermal Conductivities of, Determination of the, H. A. Nancarrow, 702
Rodents, Jumping, A. B. Howell, 623
Roebuck, Dr. John, Work of, 196
Roof Falls in Mines, Prevention of, 140
Root: Nodule Bacteria and Leguminous Plants, E. B. Fred, I. L. Baldwin and Elizabeth McCoy, 99; Studies, III, W. S. Rogers, 695
Roscoe, Sir Henry Enfield, Centenary of the birth of, 18
Ross Institute for Tropical Diseases: Activities of the, 300; Annual Report for 1932, 835
Ross: Ronald, Discoverer and Creator, R. L. Mégroz (*Review*), 40
Rotatory Power, Curious Case of Change of Sign of the, and of Mutarotation, Parisselle, 702
Royal: Academy: Lessons in Visualisation from the, Dr. Vaughan Cornish, 644; Portraits at the, 646; Winter Exhibition, 52; Aeronautical Society: award of the gold medal to Sir Richard Glazebrook, 359; award of silver medals to D. L. H. Williams and A. H. R. Fedden, 510; foundation of two medals; award of the British silver medal to Capt. C. F. Uwins, Squadron-Leader O. R. Gayford and Flight-Lieut. G. E. Nicholetts, 685; Asiatic Society of Bombay, Sir John H. Marshall awarded the gold medal of the, 683; Astronomical Society: award of the gold medal to Dr. V. M. Slipher, 91; election of officers, 236; Cornwall Polytechnic Society, 99th Annual Report, 833; Geographical Society, awards of the, 543; Danish Academy, Dr. C. Tate Regan elected a foreign member of the, 650; Dublin Society, Prof. P. A. Murphy awarded the Boyle medal of the, 683; Entomological Society of London, The, 678; Institution: Annual Meeting; presentation of portrait of Sir William Bragg, 647; gift from the Rockefeller Foundation, 686; Meteorological Society, election of officers, 200; Microscopical Society, election of officers, 128; Observatory, Greenwich, Annual Visitation, 882; Society: Mond Laboratory, Cambridge University, Opening of the, 210; Recommendations for election to the, 353; Prof. V. F. K. Bjerknes, Prof. H. W. Cushing, Prof. P. Debye, Prof. F. A. F. C. Went elected foreign members of the, 798; of Edinburgh: election of fellows, 354; award of the Makdougall-Brisbane prize to Dr. A. C. Aitken, and the Gunning Victoria Jubilee prize to Sir James Walker, 359; presentation of the James Scott prize to Prof. A. Sommerfeld, 687; of South Africa: election of officers, 22; election of officers, 687
Rubber: Industry Bill, 650; New Source of, 21; Research, 181; Dr. S. S. Pickles, 273; Bill, 576
Russia: Botany in, 554; Petroleum Production in, R. C. Beckstrom, 541
Russian Arctic Expeditions, 797
Ryegrasses, Fluorescence in, Linehan and Mercer, 474; E. W. Hullett and J. W. Calder, 475
RZ Cassiopeiæ with Eclipses, The Double System, J. Ellsworth, 850

Sabellids, Blood Circulation in, Reversible Stoppage of the, Prof. H. Munro Fox, 26
Safeguarding of Industries Act, Articles Chargeable with Duty under Part I of the, 651
Safety in Mines Research Board, appointments to the, 91
Sage Grouse, Display of, 773
Saharan Rock-Engravings, Dr. T. Monod, 551
St. Andrews University: offer by F. O. Salisbury of a replica of a portrait of Dr. E. Harkness, 372; proposed conferment of doctorates, 480; retirement of Prof. J. E. A. Steggall, 628; J. Anderson appointed professor of surgery, 848
St. Hilary's Day, 69
St. Valentine's Day, 214
Salamander Embryos, Segmentation of Spinal Nerves in, S. R. Detwiler, 739
Salmon: Fishing, E. Taverner, and others (*Review*), 42; Hatching and Salmon Migrations, Dr. W. L. Calderwood (*Review*), 42; Season; Disease, 213
Salt, Inorganic, An Optically Active, Mann, 808
Saltpetre, Chile, Origin of the, Dr. C. T. Kautter, 556
Samarium: Radioactivity of, and the Formation of Hibernium Halos, Dr. J. H. J. Poole, 654; Range of Radiation from, Prof. G. Hevesy and Dr. M. Pahl, 434
Sandfell, Laccolith and 'Dome of Elevation', L. Hawkes and Hilda K. Hawkes, 214
San Diego: Know Your, M. J. Rogers, 903; Museum, 903
Santa Monica Mountains, California, Glacial Epochs of the, Prof. W. M. Davis, 288
Schistocerca peregrina, Desert Anhydrobiosis and its Influence on the Animal Cycle of, E. Roubaud, 774
Schistosomiasis in the Philippines, M. A. Tubangui, 99
Schneider: Mediumship, Further Light on the: (*Review*), 489; Lord Charles Hope, 549; H. Price, 658; Rudi, An Account of Some Further Experiments with, a Minute-by-Minute Record of 27 Séances, H. Price (*Review*), 489
Schools and the Social Upheaval, 408
Science: A Symposium of, Prof. F. S. Marvin (*Review*), 674; Anatomy of Modern, an Introduction to the Scientific Philosophy of To-day, B. Bavink. Translated, with additional notes and Bibliography, by H. S. Hatfield (*Review*), 707; and Culture (*Review*), 707; and Service in Universities Overseas, 377; and the Textile Industry, Dr. K. Lee, 162; bequests to, Sir Dugald Clerk, 235; *Forum*, No. 1, 649; General, F. Fairbrother and E. Nightingale. Part 1 (*Review*), 420; ?, General, What is, 141; History in, 777; in the Changing World, T. Holland, and others. Edited by Mary Adams (*Review*), 674; in the Schools, 217; Irresponsibility of, Prof. H. Levy, 162; ? Is Man Ethically Fit for the Bounties of, Prof. D. D. Kanga, 233; Language in the Service of, 741; Masters' Association, Annual Meeting of the, F. C. Tompkins, 65; Museum, Photoelectric Exhibition at the, 429; Tabular Data of (*Review*), 892
Sciences, Meet the, W. M. Malisoff (*Review*), 639
Scientific: and Industrial Research, Department of, Report for Year 1931–32, 570; 669; and Learned Societies of Great Britain and Ireland, The Official Year-Book of the, 1931–1932 (*Review*), 45; and Technical Books, Recent: January 28, iii; February 25, iii; March 25, v; April 29, v; May 27, v; June 24, iii; Centenaries in 1933, Eng.-Capt. E. C. Smith, 14; Centralisation in the British Empire, Prof. C. Stanton Hicks, 397; Method, Ethical Conditions of, Bishop of Durham (Fison Memorial Lecture), 902; Progress and, 1; Professionalism, 861; Riddles, Sir J. Arthur Thomson (*Review*), 315
Scientists, A Rebuke to, Prof. A. Findlay, 1
Scotia Sea, Soundings in the, H. F. P. Herdman, 440
Scottish Marine: Biological Station, Millport, Report of the, 904; Fauna, A. C. Stephen, 446; Tectonics, Help from America in Reading, Prof. E. B. Bailey, 522
Scott's Own Expedition (*Review*), 782
'Sea: -Blue Bird of March', The, 445; -Lions in California, Breeding Season of, 885; Movements of the, Use of the Cattaneo Wave Pump for Utilising the, J. Richard, 179
Seal, Harp: Breeding Habits of the, 558; Food of the, and its Significance, 558
Sedimentation, Researches on, 394

Seed Germination, Temperature Relations of, T. I. Edwards, 404

Seeds: Germinating, of *Pisum sativum* and *Triticum vulgare*, Influence of certain Chemical Agents on the Carbon Dioxide Output of, under Optimum Germination Conditions, J. Kisser and R. Furtauer, 251; Influence of Treatment of, with Chemical Stimulants on the Cell Growth of the Rootlets, J. Kisser and J. Schubert, 251

Seismographs, Hydraulic, Prof. S. K. Banerji and K. N. Sohoni, 547

Seismology, Theoretical, Introduction to, Rev. J. B. Macelwane and Rev. F. W. Sohon. Part 2: Seismometry, Rev. F. W. Sohon (*Review*), 824

Selectivity and Radio Communication, 442

Semi-Conductors in a Magnetic Field, J. W. Harding, 731

Seric Proteins Isolated by the Acetone Method and Myxoprotein, Modification of the, A. Bonot, 106

Severn Barrage Scheme, The, 449

Sewage Purification by a New Process, G. H. Gleason and A. C. Loonam, 697

Sex: Artificial Control of, in the Progeny of Mammals, Prof. N. K. Koltzoff and V. N. Schröder, 329; Hormone, A New Crystallised, A. Girard, G. Sandulesco, A. Fridenson and J. J. Rutgers, 71; Hormones and Cancer-Producing Compounds, Dr. J. W. Cook and Prof. E. C. Dodds, 205

Sexual Cycle in the Rhesus Monkey, Dr. C. G. Hartmann, 626

Shamal, 885

Shamans and Spiritism on the Mosquito Coast, Honduras, Dr. E. Conzemius, 135

Sheep, Nutritional Condition of, and Susceptibility to Stomach Worm, A. H. H. Fraser and Dr. D. Robertson, 94

Sheffield University: Dr. G. A. Clark appointed professor of physiology, W. R. Maddocks lecturer in metallurgy, J. Dick assistant lecturer in mechanical engineering, A. J. Macdougall assistant lecturer in metallurgy, 736; Dr. L. C. D. Hermitte appointed demonstrator in pathology, Dr. E. James junior assistant bacteriologist and demonstrator; resignation of Prof. E. Mellanby and J. W. Kershaw, 884

Shrimp Industry of Leigh-on-Sea, A. L. Wells, 270

Silica: Gel, Heats of Moistening, with various Liquids, R. Berthon, 106; in the Organism and the Siliceous Particles of the Blood, L. Lemarte and E. Kahane, 523; Volatile Transport of, J. W. Greig, H. E. Mervin and E. S. Shepherd, 768

Silkstone Coal Seam of Yorkshire, 64

Silver: Arc Spectrum of, Structure of the Lines of the, D. A. Jackson, 691; Iodomercurate, F. Gallais, 215; the Life-Story of an Atlantic Salmon, R. L. Haig-Brown (*Review*), 42; Voltameter, New Form of, M. Picard and A. Stampa, 666

Size Limits, Legal, and their Effect upon Fisheries, N. B. Scofield, 831

Skiddaw Granite and its Residual Products, C. S. Hitchen, 482

Skye, Differentiated Sills in, Dr. F. Walker, 440

Skylark's Song, 105

Sleep, Agglomeration Theory of, W. D. Bancroft and J. E. Rutzler, Jr., 739

Smithsonian Field Expeditions in 1932, 721

Snails and Changes in Sea-Level, Prof. T. D. A. Cockerell, 277

Snail's Tissue, Culture of, Prof. J. B. Gatenby and E. S. Duthie, 474

Snell Memorial medal of the National Institute of Agricultural Botany, award of the, to Dr. Kenneth M. Smith, 164

Soap Film Structure, The Hydroxyl Group and, W. J. Green, 873

Social: Anthropology, Dr. P. Radin (*Review*), 315; Hygiene Congress, Sixth Imperial, 798; Study, Methods of, Sidney and Beatrice Webb (*Review*), 748

Sociological Review, Vol. 24, No. 3, Supplement to, 466

Sociology, Institute of, Incorporation of the, 33

Socrates, Before and After, Prof. F. M. Cornford (*Review*), 491

Sodium: Benzoate, Chlorination of, Dr. J. C. Smith, 28; Salicylate, Yield of Fluorescence of, P. Dubouloz, 850; Sulphite in Photographic Developing Solutions, G. Gopala Rao and Madhusudanan Pandalai, 100

Soil: Chemical Composition of the, and that of its Colloidal Contents, Relationships between the, O. Bottoni, 560; Electrical Properties of, for Alternating Currents: with Particular Reference to Radio-Frequencies, Dr. R. L. Smith-Rose, 142; Fertility, *Forest Fires in Relation to*, Prof. F. P. Worley, 787; Microbiology, Principles of, Prof. S. A. Waksman. Second edition (*Review*), 316; Scientific Study of the, An Introduction to the, Prof. N. H. Comber. Second edition (*Review*), 316; Tilling the, 141

Solanine Poisoning, S. G. Willimott, 813

Solar: Activity, a Remarkable Epoch of, H. Mémery; E. Esclangon, 559; Eclipse, Effects of, on Audio Frequency Atmospherics, E. T. Burton and E. M. Boardman, 81; Halo, A Complex, R. C. T. Evans and Dr. C. Evans, 613; Prominences at Meudon, Direct Observation of, B. Lyot, 70; 332; Radiation in Relation to its Warming Effect on the Human Body, H. M. Vernon, 737; Spectrum from 4040 to 4390 A., Microphotometry of the, Dr. R. v. d. R. Woolley, 917; System, Origin of the, A. C. Gifford, 518

Solid Solutions by Precipitation, and Isomorphism between Complexes of Platinum and of Quadrivalent Tellurium, G. Natta and R. Pirani (2), 107

Solids, Decomposition and Detonation of, Prof. W. E. Garner, 65

Soot Films and Oil, Interaction between, J. H. Coste, 691; Dr. S. C. Blacktin, 873

'Sooty Moulds' of Some Australian Plants, Eileen E. Fisher, 107

Sothic Cycle, A, Mrs. A. S. D. Maunder, 332

Sound: Films: at Chicago University, 593; Synthetic, 125; in Gases in Tubes, Velocity of, Dr. G. W. C. Kaye and G. C. Sharratt, 338; The World of, Sir William Bragg (*Review*), 860

South Africa: Geology of, Dr. S. H. Haughton, 624; Royal Society of, election of officers, 22; Vanished Races in, D. S. van der Merwe, 392; African: Culture ?, A New, Dr. E. C. N. Van Hoepen, 393; Institute for Medical Research, Report for 1931, 22; Australia, Mining Facilities in, 395; -Eastern Union of Scientific Societies, 38th Annual Congress, 919; Prof. H. L. Hawkins elected president for 1934, 920

Soviet Education, The Broad Highway of, C. A. Harrison, 920

Spat-fall and Shore Populations, 921

Spatial Distance in a Curved Space-Line, Measurement of, H. S. Ruse, 250

Spearman's General Factor, Ambiguity in Sign of, Prof. H. T. H. Piaggio, 170

Species, History of, The Bacterial Growth Curve and the, Dr. A. S. Corbet, 61

Spectral Lines in Indium and Gallium, Relative Intensity of, Miss R. Payne-Smith, 365

Spectrograph for Study of Fibrous Substances, Adam Hilger, Ltd., 844

Spectroscope, Application of the, to Biology, H. Ramage, 919

Spectroscopic Analysis by X-Rays (*Review*), 39

Spectroscopie, Handbuch der, Prof. H. Kayser und Prof. H. Konen. Band 8, Lief 1 (*Review*), 824

Spectrum: Analysis at the Massachusetts Institute of Technology, 393; Infra-Red Region of the, C. R. Bailey and A. B. D. Cassie (8), 286

Spektralphotometrie, Objective, Drs. L. S. Ornstein, W. J. H. Moll, und H. C. Burger (*Review*), 824

Spencer's Scientific Correspondence with Sir J. G. Frazer and others. Edited by Dr. R. R. Marett and T. K. Penniman (*Review*), 187

Sperm Whales in the North Atlantic, 594

Spider Crabs from Japan, Dr. Tsune Sakai, 551

Spiders: of Denmark, The (*Review*), 149; The Biology of, with especial reference to the Danish Fauna, E. Nielsen. 2 Vols. (*Review*), 149
Spike Disease in Indian Sandal, 89; 720
Spiral Nebulæ, Motion of the, Dr. Knox Shaw, 697
Sponges: Californian, M. de Laubenfels, 588; from the North-Western Pacific, Dr. Y. Okada, 279; Light-producing Powers of, Prof. E. Trojan, 728; Locomotion in, M. Burton, 356
Spray Spreaders, Present uses and Future Development of, H. Martin, 768
Spreng- und Zündstoffe: Chemische Untersuchung der, unter besonderer Berücksichtigung der zu ihrer Herstellung notwendigen Ausgangsstoffe. Unter Verwendung eines von Hermann Kast hinterlassenen Manuskriptes. Herausgegeben von L. Metz (*Review*), 186
Spring: Equinox, The, 409; Flush, The, 813; Winds and some Biological Effects, 409
Squirrel, The Grey, A. D. Middleton (*Review*), 45
'Stainless-Invar', A New Alloy, Prof. K. Honda, 587
'Standard Gold' and Silver: the Way Out of the Crisis, Dr. E. Zucker, 198
Star: Occulted by Jupiter, A, 845; of the Cepheid Type, Mean Absorption Coefficient in a Variable, G. Tiercy, 888; Influence of the Absolute Magnitude of a, on the Width of the lines of Stellar Hydrogen, P. Rossier, 483; A Variable, with Eclipses of Short Period, R. Tremblot, 815
Stars: Class *Be*, Suggested Mechanism of, D. B. McLaughlin, 739; Colour Temperatures of, 281; Composition of the (Halley lecture), Prof. H. N. Russell, 832; Double, Measures of, at the Union Observatory, Johannesburg, W. H. van den Bos, 476; Ephemerides of Variable, 590; Faint, Spectral Types of, Dr. Humason, 209; Faint, with Common Proper Motion, W. J. Luyten, 625; New Proper Motions of, from Bergedorf Observatory, C. Vick, 625; of the μ-Cephei Type, W. Zessowitsch, 137; of the Cluster *M*7, Diameter of some, Rossier, 888; of the Type *A*5, Width of a Photographic Stellar Spectrum for, G. Tiercy and A. Grosrey, 888; Variable, in the Globular Cluster M.53, 441; Radial Velocities of, Dr. P. W. Merrill, 917
State-aided Research in Great Britain, 669
Statistical: Methods for Research Workers, Dr. R. A. Fisher. Fourth edition (*Review*), 383; Tables, Dr. R. A. Fisher (*Review*), 893
Steam: Action of, on Heavy Petroleum Oils and on certain Cyclic Hydrocarbons, C. Matignon and M. Séon, 523; -Jet Operated Air Ejectors, F. R. B. Watson, 369; Tables, N. S. Osborne, H. F. Stimson, E. F. Fiock, and D. C. Ginnings, 624
Steel, Medium Carbon, Fatigue Limit of, J. W. Cuthbertson, 140
Steels: Alteration of, by Hydrogen, L. Jacqué, 36; Rustless, Measurement of the Degree of Polishing in view of the Determination of the Amount of Corrosion of, J. Cournot and Mlle. Louise Halm, 738
Stellar Spectra, Bright Lines in, 64
Stereochemie: Prof. S. Goldschmidt (*Review*), 783; eine Zusammenfassung der Ergebnisse, Grundlagen und Probleme, Herausgegeben von Prof. K. Freudenberg. Lief. 1, 2, 3 (*Review*), 563
Stereochemistry and Physics, Relations between, Prof. P. Debye (Faraday lecture), 498
Sterility in Domesticated Animals, Dr. W. Orr and Dr. F. F. Darling, 200
Stoic, The, 104
Stoke Park (R. G. Burden) Fund for Research in Mental Disorders, 159
Stone, Decay of, Relationship of Micro-organisms to the, S. G. Paine, F. L. Lingood, Freda Schimmer, and T. C. Thrupp, 178
Stork in Western Europe, J. Sokolowski, 403
Strahlenoptik, Dr. M. Herzberger (*Review*), 747
Stratosphere: New Ascent into, 614; Temperature of the, Dr. B. Rolf, 280
Strawberry 'Yellow Edge' Disease, R. V. Harris, 730
Strepsinema Stage in Reduction, Prof. H. H. Dixon, 437
Sturgeon, Spawning-time of the, 812
Styria: Eastern, Geology of, the Rocks and their Inter-Relationships, R. Schwinner, 560; Flower-Visiting Insects in, 1913, K. Fritsch, 852
Subject Index to Periodicals, 1931 (*Review*), 711
Sublimation, Inverse, O. Dony, 731
Submarine: Faulting in Kimmeridgian Times, Prof. E. B. Bailey and Dr. J. Weir, 244; Telephone Cables at Carrier Frequencies, Dr. E. W. Smith, 431; Valleys, Prof. F. P. Shepard, 331
Subsidence of London, T. E. Longfield, 558
Sudan: Anglo-Egyptian, Fossiliferous Siliceous Boulders from the, L. R. Cox, 70; Nilotic, Pagan Tribes of the, Prof. C. G. Seligman and Brenda Z. Seligman (*Review*), 345; Southern, Tribes of the, E. B. Haddon (*Review*), 345
Suffolk, East, Rural Education in, 848
Sugar in the Blood, Application of the Iodometric Method to the Estimation of, H. Bierry, B. Gouzon, and Mlle. C. Magnan, 667
Sulphates as Manure, Importance of, G. Bertrand and L. Silberstein, 215
Sulphur: and Nitrogen, Utilisation of, from Cystine at the level of Endogenous Protein Metabolism, E. F. Terroine, P. Mezincesco, and Mlle. Simone Valla, 483; Hexafluoride, Higher Homologues of, K. G. Denbigh and Prof. R. Whytlaw-Gray, 763; -Hydrogen Reaction, New Experimental Evidence in the, E. E. Aynsley, Dr. T. G. Pearson, and Dr. P. L. Robinson, 471
Sulphuric Acid, Ionisation of, Prof. H. M. Dawson, 375
Summer Thermocline in Seas and Lakes, 773
Sun, Total Eclipse of the, Aug. 31, 1932, A. de La Baume Pluvinel and D. Barbier, 922
Sun-Fish in British Waters, 665
Sunspot Areas and Numbers for 1932, 661
Sunspots: and Meteorological Phenomena, H. Mémery, 591; Earth's Influence on, P. R. Chidambara Aiyar, 245; Large Group of, 209; on the Solar Disc, Zones of Apparent Inhibition of, Prof. J. A. Carroll, 548
Supersonic: Blower, Some Results obtained with a, L. Santon, 523; Vibrations set up in a Zinc Bar undergoing Transverse Vibrations, Prof. K. Prosad and S. Sharan, 803
Surface: Catalysis (*Review*), 150; Tension and its Measurement, Dr. A. Ferguson, 66
Surrey Flora, A New (*Review*), 77
Surveying from Air Photographs, A Simple Method of, Lieut. J. S. A. Salt, 650
Suspensions Prepared starting with Proteins separated from Serum by the so-called Acetone Method, C. Achard and A. Boutaric, 178
Swallow and Cuckoo Arrive, 629
Sweden, Higher Education in, 480
Sword, They that take the, Dr. E. Wingfield-Stratford (*Review*), 635
Syllis ramosa, McIntosh Distribution of the Polychæte Worm, Dr. C. Crossland, 242
Symbols, Units and Nomenclature Commission, Conference of the, A. E. Kennelly, 775
Symmetrical Region, Variation Problems for a, Prof. H. Bateman; Prof. E. T. Whittaker, 472
Symmetry, Determination of, A Possible Source of Error in the, from Optical Extinction-Angles, M. H. Hey, 630

Tables for Statisticians and Biometricians. Edited by Prof. Karl Pearson. Part 1, third edition; Part 2 (*Review*), 893
Tabular Data of Science (*Review*), 892
Talbot's Bands, late A. C. G. Beach, 702
Talking Pictures: and Acoustics, C. M. R. Balbi (*Review*), 188; and Picture Telegraphy (*Review*), 781
Tapir, Concealing Coloration of the, 867
Tartaric Acid and Chromium, Compounds of, J. P. Mathieu, 106
Tata, Lady, Memorial Fund scholarships, award of, 920

Taxonomy and Evolution, Dr. W. H. Longley, 863
Technical: Education: F. H. Reid, 883; International Bureau of, A. Abbott and E. G. Savage appointed to act as representative and correspondent respectively, 811; Institutions, Association of Teachers in, Annual Conference, 883
Technocracy, 87
Tektites: Origin of, Dr. L. J. Spencer, 117; 596; 876; F. Chapman, 876
Television: Sir Ambrose Fleming, 539; First Principles of, A. Dinsdale (*Review*), 456
Tell: -Billa, Dr. E. A. Speiser, 806; Duweir, Palestine, Excavations at, 648; L. J. Starkey, 897
Tellurium Fluorescence, Magnetic Quenching of, R. Smoluchowski, 914
Temperature: below 0·27° K., Prof. W. J. de Haas, E. C. Wiersma, and Prof. H. A. Kramers, 719; Recorder, A New, Dr. W. Cawood and H. S. Patterson, 332
Tempora Mutantur, 105
Terns, Homing Sense of, 701
Terrestrial Magnetic Field, Diurnal Incidence of Disturbance in the, A. Crichton Mitchell, 446
Tertiary Alcohols, Dehydration of some, by Anhydrous Copper Sulphate, A. Meyer and M. Tuot, 851
Textile: Design: and Colour: Elementary Weaves and Figured Fabrics, W. Watson. Third edition, with appendices on the manufacture of Rayon (Artificial Silk) and Standard Yarns, Weaves and Fabrics (*Review*), 187; and Fabric Structure, Elementary, J. Read (*Review*), 187; Industry, Science and the, Dr. K. Lee, 162
Thallous Thiocarbonate, Preparation and Properties of, Picon, 179
Thames Valley, Lower, Deposits, 756
Theileria dispar, Experimental Suppression of Sexual Reproduction in, E. Sergent, A. Donatien, L. Parrot, and F. Lestoquard, 143
Thermal Balance of a Water Drop or Ice Particle Suspended in the Atmosphere, C. S. Durst, 35
Thermionic Vacuum Tubes and their Applications, Prof. E. V. Appleton (*Review*), 9
Thermoelectric: Elements, Construction of, A. Cotton, 559; Phenomena, A New Method of Realisation of, A. Egal, 410
Thicknesses, A Magnetic Apparatus for the Determination of, A. Bricout, 595
Thiobenzophenone, Magnetic Rotatory Dispersion of a Coloured Diamagnetic Compound, A. Cotton and M. Schérer, 215
Thiocyano- and Thio-pyrroles, and Pyrrole Disulphides, P. Pratesi, 411
Thiosulphuric Acid, Decomposition of, in Dilute Solution at the Boiling Point, E. Carrière and Mlle. Carlini, 286
Thixotropy of certain Salts, Causes of the, P. Bary, 338
Thompson: Mary Clark, medal of the Washington National Academy of Sciences, award of the, to Dr. F. A. Bather, 304; John, the Work of, 232
Thomsonite, Dehydration of, A. E. Mourant, 630
Thorium Sulphide, Picon, 70
Thought in Progress, The Play of (*Review*), 746
Thunderclouds, Penetrating Rays from, Schonland and Viljoen, 916
Thunderstorms, Summer, S. Morris Bower, 473
Tide Marks, Quantitative Studies between the, R. Elmhirst, 767
Tidal Shifts in the Earth's Crust, Dr. H. T. Stetson and Dr. A. L. Loomis, 137
Tierwelt der Nord -und Ostsee, Die, Begründet von G. Grimpe und E. Wagler. Herausgegeben von G. Grimpe. Lief. 21. Teil 1.d$_2$; Teil 2.g (*Review*), 116
Tilletia Species of Wheat in Australia in 1931, Geographical Distribution of, J. G. Churchward, 631
Timber: During Seasoning, Longitudinal Variation of, M. B. Welch, 667; Home-Grown, Census of Production of, 905; Investigations on, 847
'Time' and 'Events', Ideas of, W. W. L., 727
Time: Determination, Dr. J. de Graaf Hunter, 515; Divisions of, in use in Ancient Mesopotamia, Dr. J. K. Fotheringham, 299; Measurement: Old and New, Hope-Jones, 67; Measurements, Number 60 in: 299; Prof. H. Chatley, 914
Timothy Grass, A Fly Pest of, L. A. L. King and Miss Agnes A. Meikle, 837
Tissue Structure of Homologous Organs (Prepuce Glands) in Mice and Rats, Differences in the, J. Schaffer, 703
Tobacco Mosaic, Some Effects of the Ordinary, upon the Developmental Anatomy of the Host Plant, J. Grainger and Rachel M. Heafford, 814
Tomato Late-Blight Rot, G. B. Ramsey and Alice A. Bailey, 440
Tonfilm: Aufnahme und Wiedergabe nach dem Klangfilm-Verfahren. (System Klangfilm-Tobis.) Herausgegeben von Dr. F. Fischer und Dr. H. Lichte (*Review*), 781
Tonga Archipelago, Fishes from the, H. W. Fowler, 63
Tonphotographie: Einführung in die, photographische Grundlagen der Lichtton-Aufzeichnung. Prof. J. Eggert und Dr. R. Schmidt (*Review*), 781
Tornadoes in U.S.A., 481
Tortoise, Anatomy of the, late Dr. J. Stuart Thomson, 396
Trail that is Always New, The, W. P. Lowe (*Review*), 636
Transitory Regimes, E. Crausse and J. Baubiac, 559
Transport Problems of the Empire, W. R. Jeffreys, 126
Trans γ-Oxycrotonic Acid, R. Rambaud, 483
Tree: Growth in the Tropics, Periodicity in, Jean Schweizer, 624; Roots, Dr. E. V. Laing, 176
Trees: of Ireland, H. M. Fitzpatrick, 35; Roots of, Disintegration Action of, M. A. R. Khan, 844; Twisted, H. G. Champion, 133
Tremadoc Shales in the Tortworth Inlier, Gloucestershire, T. Smith, with notes on Fossils by C. J. Stubblefield, 214
Trematodes of Marine Mammals, E. W. Price, 243
Trevithick Centenary Commemorations, 577; 609
Triatomic Molecules, Structure of, A. B. D. Cassie, 438
Trigonometry, Elementary, Dr. J. Prescott and H. V. Lowry (*Review*), 420
Trinkler Expedition to Central Asia, The, Dr. L. D. Stamp (*Review*), 600
Trout: Brown, Spring Food of, 337; Fishing in New Zealand, Prof. E. Percival, 163; Sea, The Life of the, especially in Scottish Waters: with Chapters on the Reading and Measuring of Scales, G. H. Nall (*Review*), 42
Tsetse Fly, Control of the, R. W. Harris, and others, 463
Tumor Tissue, Application of Optical Spectroscopy to Analysis of, Winifred R. Mankin, 668
Tumours, Growth of Transplantable, in Plasma and Serum Culture Media, R. J. Ludford, 250
Tungstates, Metallic, Preparation of the, A. Karl, 923
Turbine, Early Days of the, C. Turnbull, 20
Turnips, Resistance of, to Finger and Toe Disease, 849
Turtle: Leathery, Egg-Laying of, 849; Painted, Egg-Laying and Incubation of, 849
Twins, Intellectual Resemblance of, L. Herrman and Prof. L. Hogben, 446

Uganda: Archæological Discoveries in, E. J. Wayland, 439; Stone Age Culture in, E. J. Wayland and M. C. Burkitt, 730
Ulijanowsk, Plant Geography of, H. Grosset, 696
Ultra: -filtration, Principles of, as applied to Biological Problems, W. J. Elford, 178; -Microscopic Organisms and the troubles which they cause, Sir Henry Dale, 370; -Pressures, Biological Effects of, J. Basset and M. A. Macheboeuf, 251; J. Basset, Mme. E. Wollman, M. A. Macheboeuf, and M. Bardach, 774; -Shortwave Radio Research, E. C. S. Megaw, 269; -Sonic Radiation, Chemical and Biological Effects of, Prof. A. Szent-Györgyi, 278; -Sound Waves, Measurement of the Absorption of, by Liquids, P. Biquard, 375; -Sounds, Action of, on Photographic Plates, N. Marinesco and J. J. Trillat, 667; -Violet: Light:

and Fungi, Alice A. Bailey, 404; at British Health Resorts, 91; Rays, Absorption of, by Methane, etc., W. Kemula and S. Mrazek, 106
Unemployment and the Schools, H. N. Penlington, 578
Units: Fundamental, Dimensions of, Prof. H. Stansfield, 59; Prof. F. M. Denton, 585
Universe: Expanding, Sir Arthur Eddington (*Review*), 637; Expansion of the, Milne's Theory of the, Dr. G. C. McVittie, 533; Through Wonderlands of the, R. K. Golikere (*Review*), 823
Universities: of the Empire, Year Book of the, 1933. Edited by Sir H. Frank Heath (*Review*), 710; Overseas, Science and Service in, 377; *Review*, April, 885
University: College, Cardiff: Bequest by Prof. C. M. Thompson, 372; Metallurgy Building at, 391; Degrees, Spurious, 686; Graduate, Training the, Sir Charles Grant Robertson, 268; Statistics of Great Britain, 770; Teachers, Association of, and Displaced Teachers in German Universities, 920
Unsaturated Fatty Acids, Monolayers of, Rate of Oxidation of, A. H. Hughes and Prof. E. K. Rideal, 446
Upper: Atmospheric Ionisation, Weekly Measurements of, Prof. E. V. Appleton and R. Naismith, 522; Devonian Rocks of the Chudleigh area, South Devon, L. G. Annis, 482
Ur, Ritual at, C. L. Woolley, 356
Uracil, Nucleic Acids and, Irradiation of, F. F. Heyroth and J. R. Loofbourow, 92
Uranium in Spring Waters and Deposits, Detection of, F. Hernegger, 704
Uric Acid, A New Plant Principle, R. Fosse, P. de Graeve, and P. E. Thomas, 179
U.S.A.: American Museum of Natural History, election of F. T. Davison as president and Dr. H. F. Osborn as honorary president, 236; Bureau of Standards, Annual Report of the, 394; Dr. L. J. Briggs appointed director of the, 580; doctorates conferred in, 480; Effect of the Economic Depression on Schools in, 480; Tornadoes in, 481; Forest Products Research in, 199; Legal Medicine in, 722; Local Archæological Observation in the, 868; National Academy of Sciences, award of the Alexander Agassiz medal to Dr. A. Defant, the Public Welfare medal to Dr. W. H. Park, the John J. Carty medal and award to the late Dr. John Joseph Carty, the Henry Draper medal to Dr. V. M. Slipher, and the Mary Clark Thompson medal to Dr. F. A. Bather, 754; elections to membership, 754; Naval Observatory, Publications of the, 917; Secondary Schools in, 104; Service for the Blind in, 906
U.S.S.R., Academy of Sciences, Sir Robert Hadfield, Bt. elected an honorary member of the, 272

Vacuum Technique, Laboratory, Dr. S. H. Piper, 65
Vai Script, A. Klingenheim, 915
Valoniav entricosa, Penetration of *m*-Bromo-phenol Indophenol and of Guaiacol Indophenol into, Matilda Moldenhauer Brooks, 631
Vanadium in certain Tunicates, Presence of, J. Cantacuzène and A. Tchekirian, 35
Vancouver Island, Relationships of the Mammals of, E. R. Hall, 879
Variety V_n, Concurrent Directions in a, C. Agostinelli, 851
Vegetation, Influence of Man on, Prof. E. J. Salisbury, 919
Vererbungswissenschaft, Handbuch der. Herausgegeben von E. Baur und M. Hartmann. Lief. 15 (Bd. 3, L): Entstehung der Kulturpflanzen. Von E. Schiemann (*Review*), 604
Vertebrate Skeletons, Making Whole Mounts of, M. Rahimullah and Prof. B. K. Das, 171
Verulamium 1932, Dr. and Mrs. A. E. Mortimer Wheeler, 300
Veterinary: Publications, 615; Research in the Union of South Africa, 905
Vibrating Metal Bars, Viscous Damping of, Prof. K. Sezawa, 803
Vine, Comparative Composition in the, of Homologous Leaves, H. Legatu and L. Maume, 815
Virus: Diseases, 370; and Intracellular Inclusions in Plants, Dr. F. M. L. Sheffield, 325; of Exanthematic Fevers, Passage of the, by the Digestive Canal in the Rat, C. Nicolle, J. Laigret, and P. Giroud, 375
Viscosity: Measurements of Liquids by the Oscillating Disc Method, Prof. C. E. Fawsitt, 97; of a Molten Metal, Measurement of the, by means of an Oscillating Disc, V. H. Stott, 850
Vision and Colour Vision, Dr. R. A. Houstoun (*Review*), 532
Visual: Acuity, Measurement of, R. J. Lythgoe and Dorothy E. Corkill, 98; Experience, A Peculiar, Dr. F. A. Bather, 62; Sensations, Measurement of, Dr. N. R. Campbell, 850
Vital Capacity and Occupational Characteristics, 588
Vitamin A: Absorption Spectrum of, at Low Temperatures, Dr. F. P. Bowden, S. D. D. Morris, and Dr. C. P. Snow, 582; Highly Active, Characteristics of, Dr. F. H. Carr and W. Jewell, 92; in Cod Liver Oil, An Inhibitor of the Antimony Trichloride Test for, A. Emmerie, 364; B_1, Crystal Structure of, and of Adenine Hydrochloride, J. D. Bernal and D. Crowfoot, 911; B_4 and Adenine, R. D. Heard, H. W. Kinnersley, J. R. O'Brien, Prof. R. A. Peters, and V. Reader, 617; C Activity, Indophenol Reducing Capacity of Lemon Juice and its Fractions in relation to, Dr. S. S. Zilva, 363; and Ascorbic Acid, A. L. Bacharach, 364; Constitution of, Dr. F. Micheel and K. Kraft, 274; E. G. Cox and Dr. E. L. Hirst, 402; Identification of, Prof. A. Szent-Györgyi, 225; in the Adrenal Gland, G. Bourne, 874; Methylnornarcotine, Glycuronic Acid, and, W. J. Dann, 24; Triphenylmethyl Derivative of, L. Vargha, 363; Content of Australian, New Zealand and English Butters, M. E. F. Crawford, E. O. V. Perry, and Dr. S. S. Zilva, 770
Vitamines, Les, Mme. Lucie Randoin et H. Simonnet (*Review*), 258
Vitamins: A Survey of Present Knowledge (*Review*), 857; (*Review*), 258; Bibliographical Survey of, 1650–1930, with a Section on Patents, M. H. Wodlinger (*Review*), 568; Recent Research on the, 118; Research on, A. L. Bacharach (*Review*), 857
Vivisection of Criminals, 902
Vocational Guidance and the Health of the Industrial Worker, A. Macrae, 243
Volcanic: and Tertiary Marine Series at Curlewis, near Geelong, the Older, A. Coulson, 71; Craters in the Libyan Desert, Dr. K. S. Sandford, 46; Fumaroles, G. Ponte, 923
Volcanoes, Central African, Dr. J. Parkinson (*Review*), 821
Voltages, Very High, Dangers of, 833
Vosges, Schistogreywacke Complex of the, Stratigraphic Subdivision of the, G. Dubois, 339

Wales, University of, award of doctorates, 665
Wanderers Wetterbuch: Einführung in das Verständnis der Wettervorgänge, Dr. O. Myrbach (*Review*), 786
Wapiti Deer in Wyoming, Census of, 516
War, Civilisation and (*Review*), 635
Water: Flow of, between Moving Boundaries, Cornish, 781; -Fowl and Game-Birds in Captivity: some notes on Habits and Management, A. F. Moody (*Review*), 316; -Level, Falling, in the Chalk under London, Dewey, and others, 882; Power Development, Canadian, in 1932, Dr. Brysson Cunningham, 788; Thermal Conductivity of, L. H. Martin and K. C. Lang, 813
Watt, James, Memorial Institute, Birmingham, 757
Wave: Equations and the Conservation of Energy, A. Lees, 402; -Lengths of Light and the Fundamental Standards of Length, A New Apparatus for Determining the Relationship between, J. E. Sears and H. Barrell, 192; Mechanics: Elementary Theory, Prof. J. Frenkel (*Review*), 860
Weather: Prophet: Be your Own, a Book for the Holidays and after, E. S. Player (*Review*), 712; 'Raw', Dr. G. M. B. Dobson; Sir Leonard Hill, 28; Prof. S. Russ, 131; H. E. Beckett, 132; Sir Leonard Hill, 241; Prof. W. A. Osborne, 515

World, Tabulation of, Weather, E. W. Bliss (5), 35
Webster's Collegiate Dictionary. Fourth edition (*Review*), 456
Weddell Sea, Ice in the, J. M. Wordie and Dr. S. Kemp, 916
Weed-Killers, Effect of, on the Soil, W. E. Bowser and J. D. Newton, 880
Weeds, 737
West Regional Broadcasting Station in Great Britain, 664
'Western Indian' Art, 843
Weston Standard Cell, The Temperature Coefficient of the, P. Vigoureux and S. Watts, 374
Whale Shark in the Waters around Ceylon, The, Dr. E. W. Gudger, 165 ; Dr. J. Pearson, 729
Wheat : Embryos, Nutritive Value of, V. Famiani, 107 ; -Germ Oil, Absorption Spectrum of the Unsaponifiable matter from, Dr. R. A. Morton and J. A. Edisbury, 618 ; of the Vitamin E fraction of, Dr. P. Bowden and T. Moore, 512 ; Spring, 284
White Pine Blister Rust, Fusion of Pycniospores with Filamentous Hyphæ in the Pycnium of the, R. K. Pierson, 728
Whooping-Cough, Mortality from, Dr. B. Hill, 269
Wicken Fen, The Natural History of. Edited by Prof. J. Stanley Gardiner. Part 6 (*Review*), 343
Wild Life in India, Preservation of, 779
Wind : Direction in the British Isles since 1341, Variations of, Dr. C. E. P. Brooks and Theresa M. Hunt, 814 ; Gradients, Steep, in Inversions, Breakdown of, C. S. Durst, 35 ; Over Different Surfaces, Variations in the Structure of, C. S. Durst, 814
Windle, Sir Bertram : Bertram Coghill Alan Windle, F.R.S. : a Memoir, Dr. Monica Taylor (*Review*), 307 ; Prof. W. Wright (*Review*), 307
Wireless : Echoes, Recording, at the Transmitting Station, Prof. S. K. Mitra and H. Rakshit ; R. A. Watson Watt and L. Bainbridge-Bell, 657 ; Waves, The Travel of, Sir Frank Smith, 642
Witchcraft in Africa, F. H. Melland, 195
Wood : Daily Shrinkage and Swelling of, M. B. Welch, 667 ; Moisture Content of, M. B. Welch, 524
Woods Hole Region, Mass., The Copepods of the, Dr. C. B. Wilson, 698
Wool : Fibres, Curls and Twists in, Origin of, Dr. J. E. Nichols, 201 ; Industries Research Association, Report of the, for 1932–33, 719 ; Methionine in, J. Barritt, 689
Woolly Hair in a Nordic Pedigree, Dr. O. L. Mohr, 695
Woo's Formula, An Extension of, C. Cannata, 339
World : A Vanished, Dr. A. Ferguson (*Review*), 75 ; Crisis and the Gold Standard, C. Lallemand, 70 ; Economic Conference, The, 866 ; 889 ; Order, New, The Cost of a, R. Brightman (*Review*), 183 ; Power Conference, Forthcoming, 22
Worms, Collecting and Preserving, 90

Xenohelix in the Maryland Miocene, L. Dryden, 775
Xenon, Ultra-Violet Absorption Bands of, Prof. J. C. McLennan and R. Turnbull, 214
X-Radiation, Properties of, Prof. C. G. Barkla, 166
X-Ray : Spectra, Quadrupole Lines in, E. Sègre (2), 411 ; Tube Current and Voltage, Measurement of, Dr. G. W. C. Kaye and G. E. Bell, 552
X-Rays : Diffraction of, by Liquid Sulphur, A. H. Blatchford, 813 ; Spectroscopic Analysis by (*Review*), 39

Yangtse-Kiang Flood of 1931, L. Brandt, 280
Yeast : Growth, Influence of Sodium and Potassium Ions in, Prof. I. Novi, 63 ; Permeability of, to Methylene Blue, Combined Influence of *p*H and Glucose on the, M. Junquera, 411
Yugoslavia, American Archæologists in, Dr. V. J. Fewkes, 393
Yuman : Ethnology, E. W. Gifford, 915 ; Music, Miss Densmore, 98

Zea Mays, A Correlation of Ring-shaped Chromosomes with Variegation in, Barbara McClintock, 631
Zentral-Asien und Karakorum-Himalaya, Geographische Forschungen im westlichen, Dr. E. Trinkler (*Review*), 600
Zeolites, The, M. H. Hey (5), 630
Zinc Oxide : and Anhydrous Zinc Chloride at High Temperature, Behaviour of Mixtures of, A. Ferrari and G. Trampetti, 339 ; Fluorescence of, Beutel and Kutzelnigg, 917
Zoological : Advice to the State, Importance of, Dr. J. Gray, 88 ; Expedition to Morocco (1930), Results of a, F. Werner and R. Ebner, (5), Scorpions, 287 ; Gardens : Indian Rhinoceros at the, 683 ; New Gorilla House at the, 646 ; Society of London, Report for 1932, 755
Zoologie : Handbuch der, eine Naturgeschichte der Stämme des Tierreiches, Gegründet von Prof. W. Kükenthal. Herausgegeben von Dr. T. Krumbach, Bd. 2 : Vermes Amera, Vermes Polymera, Echiurida, Sipunculida, Priapulida. Lief. 11 ; Bd. 2, Lief. 12, Lief. 13 ; Bd. 2, Lief. 14 ; Bd. 3, Halfte 2 : Chelicerata, Pantopoda, Onychophora, Vermes Oligomera. Lief. 1, Teil 3 ; Lief. 2, Lief. 3 ; Bd. 6 : Acrania (Cephalopoda), Cyclostoma, Ichthya, Amphibia. Hälfte 2, Lief. 1, Lief. 2 ; Bd. 7 : Sauropsida, Allgemeines ; Reptilia ; Aves. Hälfte 1, Lief. 1 ; Bd. 7 : Sauropsida, Allgemeines ; Reptilia ; Aves. Hälfte 2, Lief. 6 (*Review*), 222
Zoology, Descriptive (*Review*), 222
Zurich University, Centenary of, 684

Supplements should be collated and bound with the numbers with which they were issued.

Progress and Scientific Method

AMONG the misfortunes of this present age are the tendencies of the Press to seize on the sensational in the business of science, and of the public to expect such sensational pronouncements. This, equally with the absence of an adequate scientific element in our general educational system, of which the first is indeed a consequence, is mainly responsible for the general failure to understand the scientific spirit and the place of science in our civilisation.

Unquestionably, extravagant claims have been made alike regarding the contribution of science to general welfare and the part which men of science have to play in the State and in the general life of the community, and such claims have done great disservice to the cause of science. The evidence, however, does not indicate that in the main such claims have emanated from scientific workers themselves. They have more frequently been due to the journalistic quest for the sensational, to the quotation of impressive passages in the utterances of a man of science apart from the qualifying context. Of this danger the treatment recently accorded to a scholarly address by Prof. A. Findlay to a joint meeting of the Manchester chemical societies is a pertinent illustration. Under the headlines of "A Rebuke to Scientists" it is hard to recognise the thought-provoking address of Prof. Findlay with its wide sweep and philosophic temper, recalling at times the presidential address of General Smuts to the British Association in 1931. Prof. Findlay stressed the idealistic value of science rather than its material results and suggested that the real claim of science to a wider recognition and cultivation in the community is based on such values. The spirit of science, as expressed in the quest for truth, is an essential element complementary to beauty and goodness in the perfecting of humanity, and its inculcation should form an essential element in our system of education.

This plea for science as an essential element of culture and not as part of a technical training was, however, ignored by those who fastened on his refutation of the claims of scientific workers to a privileged position in national administration. Unfortunately, Prof. Findlay himself made one or two incautious remarks which have tended to offset his admirable presentation of a point of view which scientific workers themselves have often been prone to overlook, owing to the widespread neglect of the teaching of the philosophy of science or the scientific outlook in the universities. Few scientific workers with any experience of industry would, for example, care to endorse the statement that, so far as industry is concerned, the battle for scientific control is already won. The position of the Cotton Industry Research Association in the very city in which the lecture was delivered should have been sufficient reminder of how very far we are yet from a general acceptance by industry of the importance of research as an essential element in industrial efficiency and advance. Similarly, so far as national administration is concerned, without pointing to a host of matters in which the neglect of technical factors and scientific opinion has been conspicuous, it is sufficient to recall that the report of the Bridgeman Committee on the Post Office issued recently was the first public inquiry committee to give full recognition to the scientific expert in the Civil Service scheme of things. Only in this report was it recognised officially that the scientific expert is entitled to participate on level terms with the administrative expert and the financial expert in the formulation of policy.

If the principle has been conceded, the application here and elsewhere has yet to be worked out, and those who most welcome Prof. Findlay's insistence on the cultural value of science will most regret his untoward suggestions regarding the capability of men of science for administrative work or the extent to which they have been accepted in such positions. While Prof. Findlay's protest against the mechanisation of industry and his warning against the dangers of materialism and an excessive emphasis on mechanical efficiency will be warmly welcomed, the influence of science on industry has scarcely been either so materialistic or so mechanising as he implies. On the contrary, the application of scientific methods of management characteristic of large-scale industry pays an attention to the human factor which was formerly rarely encountered. The results which have attended the investigations of the National Institute of Industrial Psychology or of the Industrial Health Research Board already attest the humanising effect which applied science can exert on industrial conditions. Moreover, the increasing attention which is being directed to the theory of management has already emphasised the importance to efficient administration of encouraging the development of individual responsibility, the expression of personality and the organisation of the team spirit.

It is indeed here that Prof. Findlay's address is most open to criticism. So far from human nature being intractable to the scientific method, the evidence suggests that one of the most urgent needs of to-day is an adequate attack on the social sciences and a determined attempt to place sociology, economics, psychology on a really scientific basis. Much patient research in anthropology and human biology will be required before this can be achieved, and it is highly probable that the most important contributions of science to human welfare during the next few decades will come from such fields as these, which enable us to understand and interpret more accurately the human factor and our social, economic and industrial problems.

Apart altogether from these considerations, Prof. Findlay's dislike for extravagance has led him to overlook the essential challenge presented by such spokesmen as Sir Alfred Ewing and Prof. Miles Walker. The failure of our present administrative methods to which our economic and international difficulties bear witness, and of which the bankruptcy of the Disarmament Conference is a recent example, had led many others besides men of science to wonder whether methods in which action is determined less by political prejudice than by dispassionate analysis of the ascertained facts may not offer better hope of success. The disposition to accept the leadership of science is prompted by a growing realisation of the extent to which scientific and technical factors enter into all our problems in this scientific age and that, if such factors are only one aspect of our problems, they present an aspect which demands accurate assessment and intelligent action if disaster is to be avoided.

This point of view does not suggest that numerous other considerations are not involved in an administrative decision. It does, however, contend that the scientific worker who possesses administrative ability as well as the capacity to assess the technical facts is at least as likely to arrive at a sound decision, as those without such scientific knowledge and training, and that the openmindedness and willingness to face change associated with the scientific outlook is an important and hopeful element at the present time. The situation is so serious that accepted doctrines in finance, economics, politics are being questioned and must stand their trial as every scientific theory has to do in the advance of science.

Scientific management stands essentially for the substitution of exact scientific knowledge for opinions or rule of thumb methods, and not for the disregard of essential elements in a problem, whether those elements are or are not what is usually described as technical.

Even in industry, such exact scientific knowledge involves to an increasing extent a re-examination of the whole of our economic and indeed of our political machinery and ideas—a re-examination conducted much in the spirit of an engineer faced with a problem in factory or office management and concerned solely with the issue of improving those arrangements so as to secure a higher standard of living for the community. The world believes that the advancement of objective and exact knowledge is inevitable and ultimately beneficial and that the problems of distribution and finance, for example, so long treated in haphazard and fatalistic fashion, will yield to exact knowledge.

It can accordingly scarcely be questioned that in the modern State the scientific expert will occupy a position of increasing responsibility, and the security of our civilisation largely depends upon the efficiency and expedition with which methods are worked out for permitting his effective participation in public as in industrial affairs. Possibly the solution may be found along lines visualised by General Smuts, and the nations learn to look to the organised system of the expert report and accept as a matter of course, just as judicial decisions are accepted, the authoritative and impartial lead which it gives.

An important factor, however, is bound to be the general outlook of the scientific worker himself. His specialist knowledge of one particular field must be joined to a sense of values, a wide outlook and a public spirit which induce him to place his services to a greater extent at the disposal of society. In the leisure State there should be no room for the excessive specialisation and narrowness of outlook deplored by Prof. Findlay, and it should be possible so to re-organise our training that the cultural value of scientific thought and method is imparted to the student, and the tendency of scientific workers to regard only their special field from a scientific point of view counteracted. Only as scientific workers are prepared to regard the whole domain of life from a scientific point of view and to support as a body those who at particular points are seeking to extend the application of scientific method and the scientific spirit, substituting facts for prejudice, opinion or guesswork in determining action, can we hope for decisive advance. Both the organisation and the functioning of the State must become more scientific, impartial, businesslike and less purely political, and the scientific expert is unlikely to receive his fitting place in the new order without organised support from his fellows as well as keen and intelligent criticism.

Prof. Findlay has done well to remind us that science is more than a body of results and truths. Great as are the benefits which mankind has derived from scientific discoveries, from the new knowledge which science has made available, there are greater services to be rendered. Science has yet to teach man how to use that knowledge, to impart generally that attitude, outlook or method of acquiring knowledge which is essential if mankind, individually or collectively, is to adapt himself to the new conditions. Science alone, indeed, will not save mankind from disaster, invaluable as can be its contribution to the fundamental thinking required. But the balanced wisdom and judgment so imperatively demanded to-day can only be attained as science is regarded not as a storehouse of facts to be consulted from time to time but as one of the great human endowments, to be ranked with art and religion, and the guide and expression of man's fearless quest for truth. This outlook can only receive adequate recognition as more and more in their own personality scientific workers exemplify the unifying power of the spirit of science and its contribution to the ordering of every sphere of conduct on a basis of truth and not prejudice.

Properties of the Atom

The Interpretation of the Atom. By Prof. Frederick Soddy. Pp. xviii+355+20 plates. (London: John Murray, 1932.) 21*s.* net.

FEW discoveries, if any, have influenced so rapidly and deeply physics, chemistry and many kindred sciences as that of the spontaneous disintegration of radioactive elements. The development following this discovery attracted also the lay mind, which was struck by the idea of evolution of inorganic matter and by the far-reaching conclusions in the field of geology and cosmology, to which the application of the science of radioactivity led. The layman's interest was enhanced by the spectacular sides like that of electroscopic discharge at the approach of the experimenter carrying radium in his pocket or suitcase, by the radium clock, and, by no means least, by the possibility of the medical application of radium rays against both tedious and fatal diseases.

The general reader interested in the great advances in our knowledge of the nature of matter and its manifold applications has every reason to be highly indebted to Prof. F. Soddy for his "Interpretation of Radium", first published in 1909. It is a most instructive task to compare the above mentioned book with "The Interpretation of the Atom", prepared by Prof. Soddy to take the place of the first mentioned volume, which has long been out of print. Even the reader familiar with atomic physics and chemistry will be struck when reading this account of the unparalleled progress made by these sciences in the last three decades. Part I deals fully and systematically with the remarkable series of spontaneous disintegration of the atom, while in Part II the general progress of atomic chemistry is discussed. A chapter on cognate geological and astronomical aspects and the cosmic radiation concludes the volume.

Prof. Soddy is known as a thinker and writer of unusual originality, who does not hesitate to oppose himself, even to ideas accepted by most of his contemporaries—a characteristic quality which, coupled with genius and lucidity, is undoubtedly responsible for his greatest achievement, the introduction of the conception of isotopes. The reader will therefore not be astonished to find Prof. Soddy in pronounced opposition to the mathematical presentation of physical theories in the age of great successes of quantum mechanics, and to learn that he is not among those who can "bow down and worship the square root of minus one". "The Interpretation of the Atom" is primarily intended for the general reader, but it will undoubtedly prove to be a helpful guide to scientific students of all grades; while the man of science interested in the history of this subject will also find matter of interest to him.

The development of scientific thought and progress often follows roundabout paths, which even the onlooker has difficulty in following; not a few scientific workers are inclined, therefore, to the view that the official history of the development of scientific thought not seldom differs materially from the actual course of events. Two examples may be cited, Bohr's fundamental conception of the atomic structure, and the development of the notion of atomic numbers, both outstanding events in natural philosophy, and the development of which are usually described in a way which differs materially from the actual facts. We mostly read that Bohr's conception was due to the effort to explain the appearance of spectral series. It would go too far to pretend that Bohr (who not long before passed his examination with first class honours) would not know of the existence of spectral series, but these were certainly not in the forefront of his thoughts when he first embarked on the philosophy of the atom. It was only at a later date, that in discussing experimental results obtained by one of his Copenhagen colleagues, he noticed the possibility of applying his new conception to explain the appearance of spectral series.

The actual development was as follows. Bohr was deeply struck by Rutherford's conception of the nuclear atom, realising simultaneously, however, the impossibility of reconciling this conception with the requirements of the classical theory of radiation. The most direct step would have been to discard Rutherford's conception; Bohr chose another path and introduced Planck's quantum idea in place of the classical conception, when interpreting the stability of the nuclear atom. By doing so he was led at once to the fundamental distinction between the nuclear and electronic properties of the atom, to the identity of the atomic number and nuclear charge and also to the conclusion that the emission of the disintegration β-particles has its origin in the nucleus. The latter led him to the conclusion that, for example, when an atom of thorium loses consecutively one α- and two β-particles, the thorium atom reappears, and he arrived thus at the displacement laws, as a special case of a much wider generalisation. Bohr discussed this result widely without publishing it. These laws were, as is well known, published later by different men of science as an empirical summary of the experimental results of Fleck and others. That the sequence of the elements in their natural system, that is, the atomic number, is identical with the number of the nuclear charge, was published by Bohr at an early date when basing his first calculations on the assumption that the hydrogen nucleus has one, the helium nucleus two, elementary charges, and so on.

The above narrative of the introduction of the conception of the atomic number would, however, not be complete without mentioning that this conception emerged, simultaneously with Bohr's deductive line of thought, in the Manchester physics laboratory on inductive lines. Geiger and Marsden checked completely Rutherford's theory of large scattering of α-particles and found the nuclear charge of gold to be about 100. This result was not at all unexpected, as early theories of α-ray scattering and stopping had suggested already that there should be half as many electrons in the atom as its weight. When Moseley started his work which became the foundation of a new and important branch of physics, the conception of atomic number was thus clearly developed. We owe to Moseley's genius a simple method of determining the atomic number of each element and of fixing exactly the number of elements between hydrogen and uranium. From the fact that the nuclear charge of gold was found to be 100, and also from the chemical evidence, it followed already that the number of unknown elements could only be a very restricted one. The actual number was, however, fixed by Moseley.

The introduction of the conception of the atomic number impressed contemporary scientific workers so deeply that its rival conception, that of atomic mass, seemed for a while to be deposed from its long reign. Through Aston's work and the development of later years, contemporary interest is again focused on atomic mass and thus equal rights are secured for these two fundamental properties of the atom.

Every reader interested in the problems and the progress of natural science will find Prof. Soddy's book most fascinating reading. G. HEVESY.

Chromosome Mechanics

(1) *Recent Advances in Cytology.* By Dr. C. D. Darlington. Pp. xviii + 559 + 8 plates. (London: J. and A. Churchill, 1932.) 18*s.*

(2) *Chromosomes and Plant-breeding.* By Dr. C. D. Darlington. Pp. xiv + 112. (London: Macmillan and Co., Ltd., 1932.) 7*s.* 6*d.* net.

THE discovery that the chromosomes are the bearers of the hereditary units (genes) has led to a renewed interest in their study by cytological methods. There has developed a vast literature, much of it based on correlated studies of cytology and experimental genetics. Dr. Darlington has worked through this literature, and has attempted in the larger of the two works under notice not only to describe the more important recent results but also to provide a unified general scheme of chromosome behaviour.

This general scheme is based on several fundamental hypotheses. The first of these is that like chromosomes (or parts of chromosomes) are regularly attracted in pairs, and that the attractive force is satisfied when two like parts come together, so that more than two are not attracted. This leads directly to an interpretation of the difference between mitosis and meiosis. At mitosis each chromosome is already split into two daughter chromatids at prophase. These lie side by side and thus satisfy the attractive force. At meiosis the division is delayed, and attraction therefore causes homologous chromosomes to conjugate. Division now follows, and there result four chromatids instead of two chromosomes; these are no longer attracted except in pairs, and at each level there results a separation into two groups of two chromatids each. Observation shows, however, that this separation does not occur between the same pairs of strands at each level, so that there are chiasmata, or crossed strands, at certain points. Darlington argues that it is these chiasmata that maintain the unity of the quadruple structure until metaphase, and thus insure regular segregation. In the absence of chiasmata the chromosomes merely fall apart into two separate pairs, and these segregate at random at the first division.

According to Darlington, each chiasma results from a crossing over. The initial separation of two chromatids from two others is reductional at every level, that is, the two chromatids derived by division of a single chromosome always remain associated. If two that are not sisters have undergone mutual exchange at a given level, there results a chiasma at that level.

These are Darlington's main theses; meiosis is mitosis with delayed division of the chromosomes, chiasmata result from crossing over, and metaphase pairing is due to chiasmata that prevent separation of divided homologues. He interprets the whole range of chromosome cytology and genetics on the basis of these views. There is a logical and detailed marshalling of an almost overwhelming body of evidence, much of it based on Darlington's own novel and extensive investigations. This evidence relates not only to careful analysis of the normal behaviour of a very wide variety of animals and plants, but also more especially to unusual cases—polyploids, extra-chromosome types, hybrids, and mutant differences in chromosome behaviour.

The reviewer finds himself strongly inclined in favour of two of the main hypotheses—those concerning the nature of meiosis and the effect of the chiasmata in holding homologues together until metaphase. The first of these is contrary to the observations of some cytologists, who have reported that the chromosomes divide before the meiotic conjugation; but Darlington's view has an attractive logical simplicity that makes it difficult to think of the phenomena in any other terms. Acceptance of these hypotheses involves also acceptance of the more fundamental hypothesis of attraction by twos and not by larger numbers. But it does not necessitate acceptance of Darlington's interpretation of the origin of chiasmata. This hypothesis leads to certain contradictions with the genetic data, which to the reviewer seem fatal to the hypothesis. The occurrence of regular pairing in the male *Drosophila*, in which there is no crossing over, makes it clear that chiasmata are not necessarily associated with crossing over—a conclusion avoided by Darlington only by the expedient of very special and improbable accessory hypotheses. It follows that chiasmata are not due to crossing over, and one may turn to the alternative view, referred to by Darlington as the "classical hypothesis". On this interpretation the initial separation is not always reductional, that is, at certain levels sister chromatids separate. If the separation is in different planes at successive levels, a chiasma will result between these levels. If the initial separations are permanent, crossing over will result (after, not before, the chiasma is formed), but it is possible that, at times, the original separation plane may be only temporary, the chiasmata simply unravelling without leading to crossing over. On such a basis it appears to be possible to give a self-consistent account of the genetic and cytological phenomena.

Evolutionary discussions occupy much space in Darlington's book. His view is that chromosomes are especially favourable for the construction of evolutionary schemes, because their materials control the gross structure of the organism but are not themselves controlled by the rest of the organism, and for several other reasons. The discussion of the evolution of chromosomes and chromosome systems is interesting and at times stimulating; but to one who has studied the period in the history of zoology when the making of hypothetical phylogenies was popular, there is a familiar sound to the argument. There are many who will hope that we are not to see a revival of the fashion of constructing elaborate hypothetical histories that must for ever remain hypothetical.

This is a difficult book. It is closely argued, and so full of facts and ideas as to require slow and careful reading. It will be indispensable for the student of cytology or genetics, but the more general reader will find the smaller book easier to assimilate. This, as its title indicates, is written for the plant breeder; but anyone interested in the new results obtained by the cytological study of polyploid and hybrid plants will find here an admirable and readable summary.

A. H. STURTEVANT.

Modern Physic

(1) *The British Pharmacopœia, 1932.* Published under the direction of the General Council of Medical Education and Registration of the United Kingdom. Pp. 1 + 713. (London: Published for the General Medical Council by Constable and Co., Ltd., 1932.) 18*s.* 6*d.* net.

(2) *The Extra Pharmacopœia of Martindale and Westcott.* Revised by Dr. W. Harrison Martindale. Twentieth edition. In 2 vols. Vol. 1. Pp. xlviii + 1216. (London: H. K. Lewis and Co., Ltd., 1932.) 27*s.* 6*d.* net.

(1) THE duty of preparing "The British Pharmacopœia" was laid upon the General Medical Council by the Medical Act of 1858 and the Medical Council Act of 1862. Since then five pharmacopœias have been issued at irregular intervals varying from three to eighteen years. The present issue is the sixth and in future

revision will take place every ten years. It is explained in the preface that the "Pharmacopœia" includes only the more important "standard articles, which are in use throughout the Empire" and with characteristic British elasticity in governance, provision is made for the issue of supplements or addenda by Governments of overseas parts of the Empire, who may desire to sanction the use of drugs with a local reputation. This is a happy solution of a long-standing difficulty.

The Commission upon which the actual work of preparing the "Pharmacopœia" devolved, was assisted in its labours by a group of sub-committees on clinical medicine, pharmacy, pharmacology, pharmacognosy and pharmaceutical chemistry, whilst the decision for or against biological standards for ergot, cod liver oil, digitalis and strophanthus, arsenobenzene derivatives and similar products, chemical control of which is still doubtful or impossible, necessitated the appointment of eight subsidiary committees, one for each subject of potential biological standardisation.

The revision of a pharmacopœia involves three branches of work, the elimination of drugs which have become redundant or obsolete, the selection of such recent contributions to *materia medica* as have found a sure footing in clinical medicine, and the definition of each item in the final list. In the new "Pharmacopœia" the omissions are far more numerous than the additions. They are chiefly galenical preparations, some of which are replaced by more modern examples of the pharmacist's art, some crude vegetable drugs, a number of compounded medicines and a few synthetic, pharmaceutical chemicals. No serious objection can be raised to any of these omissions, especially as the articles concerned will still figure in the British Pharmaceutical Codex, the revision of which is now in progress. Indeed this process of elimination might have been carried further. Eucalyptus oil (cineole, 70 or more per cent), cajuput oil (cineole, 50 to 60 per cent) and eucalyptol (cineole, 97·5 per cent) are presumably all included for the sake of their cineole content, this being the component indicated by the prescribed assay, and if so, two of them are redundant.

The additions include several well-known alkaloids, quinidine, ephedrine, ergotoxine and emetine, which have found new and important medicinal applications since 1914, a number of synthetic drugs, including a choice of local anæsthetics, and hypnotics and the indispensable antisyphilitics, neoarsphenamine and sulpharsphenamine. The most notable addition is the group of biological products including insulin, liver extract, Schick control, Schick test toxin, diphtheria prophylactic, antityphoid-paratyphoid vaccine, gas-gangrene antitoxin, and antidysentery serum. Apart from this biological innovation, it cannot be said that any striking change has been made in the list of officially recognised drugs. Some notable candidates for recognition have probably been omitted because they are patented products, others because their present reputation may be based on pioneering enthusiasm and they have still to run the gauntlet of extended clinical trial, which will eventually bring them to their proper places in practical therapeutics.

The list of official drugs, which emerges by the operation of these two kinds of selection, is essentially a matter for comment by clinicians, but if a chemist may venture two opinions upon it they are, that the list is what a list of officially-recognised drugs should be—safe, sound, and not too conservative—and that it is satisfactory because due weight has been given to the pharmacological and chemical evidence for and against each drug.

It is in the third branch of its labours, the definition of the selected products, that the Commission has most clearly improved upon preceding pharmacopœias. Much more attention is given to tests for identity and for degree of purity, to the analysis of chemicals and to the assay of potent galenical and biological preparations. In the 1914 Pharmacopœia the appendices amounted to over eighty pages: in the new issue nearly twice that space is occupied, due mainly to the inclusion of more descriptions of biological, chemical and physical methods for the determination of the quality of drugs, using that term in a broad sense. These appendices now form a useful and interesting manual of methods of assay, which may even find a place for the Pharmacopœia in laboratories not directly concerned with medicinal products.

Daily use of the sixth" British Pharmacopœia" will inevitably reveal minor weaknesses, but taken as a whole it is a satisfactory and in many ways a model contribution to the world's collection of national pharmacopœias. The nation has every reason to be grateful for the labours of the Pharmacopœia Commission, for the time and knowledge which the committees of experts have expended and for the accumulated results of technical experience which manufacturers have given just as freely. The least it can do in return is to provide for that continuity of investigation which will lighten the work of preparing the Pharmacopœias of the future.

(2) When a technical work has reached its twentieth edition in the course of less than half a century, it may be assumed that the author knows much better than any merely ephemeral reviewer, what his particular public requires and in what form to give it to them. This is the case of the "Extra Pharmacopœia". The book is fittingly noticed here because it provides the medical practitioner with the information he needs about the latest developments in therapeutics and thus facilitates that extensive clinical experimentation with new *materia medica*, the results of which alone can finally determine their real value. It thus serves the cause of medical progress and at the same time admirably fulfils its main purpose as a handy and singularly complete reference book for the multifarious needs of the pharmacist and the medical man. In these respects the twentieth edition is as good and as up to date as its predecessors were in their day, and those who know the "Extra Pharmacopœia" need no further commendation. T. A. H.

Short Reviews

The Outline Series. *The Physical Nature of the Universe.* By J. W. N. Sullivan. Pp. 143. *Theories and Forms of Political Organisation.* By G. D. H. Cole. Pp. 160. *Modern Theories and Forms of Industrial Organisation.* By G. D. H. Cole. Pp. 159. *An Introduction to the Study of Sex.* By Prof. F. A. E. Crew. Pp. 160. *An Introduction to Psychology.* By Prof. F. Aveling. Pp. 176. *An Introduction to Finance.* By Prof. T. E. Gregory. Pp. 144. *An Introduction to Economics.* By Maurice Dobb. Pp. 143. *The Arts of Painting and Sculpture.* By Roger Fry. Pp. 160. *An Introduction to Psycho-Analysis.* By Prof. J. C. Flügel. Pp. 159. *The Theory and Practice of Architecture.* By Prof. C. H. Reilly. Pp. 144. *Principles of Literary Criticism.* By Prof. Lascelles Abercrombie. Pp. 160. (London: Victor Gollancz, Ltd., 1932.) 1*s.* 6*d.* each.

ONE of the more hopeful signs, indicating the approach of an age in which knowledge and power are more closely and harmoniously related, is the reception afforded to the various summaries or outlines of modern knowledge which have appeared in recent years. The publication in separate parts of eleven of the essays by acknowledged authorities which formerly appeared as a composite book under the title "An Outline of Modern Knowledge" is evidence of this demand and the publishers are to be congratulated on the step they have taken in place of issuing a new edition of the composite work.

The publication as individual essays is free from several objections which may be brought against the combined treatise. The essays can be seen as the introductory monographs which they really are and the impression of a reference book is destroyed. The lack of proportion in the original book is less conspicuous in the separated monographs and could indeed easily be remedied by the publication of supplementary volumes to fill the more serious gaps, so far as they are not found in the reprinted monographs themselves.

Handbuch der Pflanzenanalyse. Herausgegeben von G. Klein. Band 2: *Spezielle Analyse.* Teil 1: *Anorganische Stoffe; Organische Stoffe, I.* Pp. xi + 973. (Wien: Julius Springer, 1932.) 99 gold marks.

A KNOWLEDGE of the constituents of plants is becoming both of increasing importance and difficulty, as their number continues to grow, and it is, therefore, of value to have a work of reference which, on one hand, lists the various products according to some logical scheme, whilst on the other, it describes the methods for their identification and analysis. Working in conjunction with the index of nearly ninety pages, it is possible rapidly to have the requisite information about any desired compound.

The book is necessarily the result of collaboration, no less than twenty-three different authorities being responsible for the several sections. The first quarter of it deals with the inorganic constituents of plants including the nitrogen compounds, also the analysis of plant ash and gas: it is done with great attention to detail but in a suitably concentrated form. There follows the organic section divided up into groups of allied substances as is customary: it is this part which will be found of immense value to all active workers in the domain of plant chemistry.

The matter is highly condensed but contains just the information which is usually needed, and the text is not overburdened with countless references to the original literature, which the seeker must find in certain other works indicated, should he require them. Taking the section headed "Phenols" for example: the systematic occurrence in indicated plants is given for 61 phenols, 10 quinones, 11 anthraquinones. The general properties and colour reactions of phenols are described with a note as to the properties and derivatives of each individual phenol, the whole giving the complete state of knowledge in this particular field, which it would otherwise take a great deal of reading to survey.

Climate: a Handbook for Business Men, Students and Travellers. By Dr. C. E. P. Brooks. Second edition, revised. Pp. 199. (London: Ernest Benn, Ltd., 1932.) 10*s.* 6*d.* net.

AN early second edition testifies to the general utility of Dr. Brooks's handbook. All parts of the globe are dealt with, and a useful feature at the end of each regional division is a table furnishing for a number of selected places data of temperature, humidity, rain, snow and thunder. There are very few illustrations, and, perhaps, it is a recommendation that the book is not encumbered by a lot of commonplace maps and diagrams.

The treatment is essentially statistical, but Dr. Brooks knows his subject too well to allow his outlook to be blinded by the data which he wields. This is an important matter because climatology as a science has suffered badly from the mishandling or misinterpretation of the very data on which it largely depends.

The book is, however, not so free from loose statements as is to be expected in a second edition. For example, a statement, to the effect that it is the relative humidity which gives the 'feel' of the air, seems to us to be faulty. The 'feel' of the atmosphere is an intricate complex of temperature, wind, radiation, moisture and probably, also, obscure influences like electricity; but, so far as humidity is concerned, it is surely the absolute humidity or vapour pressure as controlling the rate of evaporation from the body which is the important factor, not the relative humidity except at saturation point with fog. Thus on an enervating summer day of high vapour pressure the relative humidity is often much lower than on a bracing winter day of low vapour pressure. L. C. W. B.

Faith, Hope and Charity in Primitive Religion. By R. R. Marett. Pp. vii+181. (Oxford: Clarendon Press; London: Oxford University Press, 1932.) 10*s.* net.

DR. MARETT'S Gifford lectures for 1931–32, an expanded form of lectures delivered under the auspices of the Lowell Institute of Boston in the previous year, have as their theme the evaluation of the religious experiences of peoples of the lower culture, or as Dr. Marett prefers to call them, savages. It must not be thought, however, that Dr. Marett would regard anthropology as one of the normative sciences and that he would attempt to apply an ethical scale to primitive ideas of behaviour. His evaluation is biological in the sense that its aim is to test survival value. The various activities of the savage are passed in review one by one and analysed with the view of the isolation of their emotional content—savage religion being a matter of the emotions rather than of intellect or of action. Dr. Marett then proceeds to show that the religious emotions which colour the whole range of savage activity on the whole make for the virtues or qualities which he designates "Faith, Hope and Charity" and regards as the effective element in the contribution of religion to the advancement and survival of man. A brief summary does less than justice to the acuity of Dr. Marett's vision—it may be suspected that at times he finds his material a thought intractable. Nor is it possible to do more than refer to the insight shown in the many valuable suggestions on controversial points which he throws off, almost casually, in the course of his argument.

Thermionic Vacuum Tubes and their Applications. By Prof. E. V. Appleton. (Methuen's Monographs on Physical Subjects.) Pp. vii+117. (London: Methuen and Co., Ltd., 1932.) 3*s.* net.

THE student with a good knowledge of general physics will find this volume very helpful in studying radio-frequency phenomena. Modern thermionic tubes have so many important applications in physics and electrical communication that a knowledge of their action and how they are constructed is essential to almost every research physicist and electrical engineer. The author writes carefully and clearly, so the ordinary reader easily grasps the laws which govern the emission of electricity from hot bodies and how to apply Richardson's formulæ to make calculations. He then explains the internal action of the two electrode tube (diode) and states some of its applications. Finally he discusses the three electrode tube (triode) and describes its applications as an amplifier, a rectifier and an oscillation generator. The book can be recommended to the experienced amateur in radio communication as a scientific introduction to the subject as well as to the physicist and mathematician who intend to read the relevant parts of advanced treatises well before following up some line of research.

The Practical Treatment of Diabetes. By Dr. T. Izod Bennett. Pp. ix+107. (London: Constable and Co., Ltd., 1931.) 6*s.* net.

THIS book is a brief and severely practical account of the modern method of treating the diabetic. References to theory are few and are limited to such details as are absolutely necessary to explain the therapeutic steps. A short chapter is devoted to diagnosis, the second and third to general principles of treatment and dieting, the fourth to the use of insulin, and the remainder of the book to complications and special problems and considerations. As described by Dr. Izod Bennett, the restoration of a diabetic to such condition that he is sugar-free on sufficient diet appears an easy matter, and the general practitioner who has not had to deal with many cases will learn with surprise that this object can be attained almost invariably within three weeks. How it can be done is clearly set out in some fifty pages of this book, which, as a practical guide, lacks no essential features. Specimen diets during treatment, and food tables showing the great variety finally available, are included.

Mount Everest

By Col. H. L. CROSTHWAIT, C.I.E.

MOUNT EVEREST, everyone knows, is the highest mountain in the world. It was discovered, and its height determined, during the operations of the Great Trigonometrical Survey of India in the course of carrying out the geodetic triangulation of that country in the years 1849–50. The figure adopted, namely, 29,002 ft. above mean sea level, was derived from the mean of a large number of vertical angles observed to the peak from six different stations situated in the plains of India south of Nepal. These stations were at distances varying from 108 to 118 miles. It was not until some months afterwards, when the necessary computations had been completed, that the great height of Everest was first realised. The actual discovery was made in the computing office at Dehra Dun.

The determination of height above mean sea level by the method of vertical angles, observed from one station only, involves the assumption of a coefficient of refraction—always a doubtful quantity, especially where great differences of height are concerned as in the present case—and also a knowledge of the amount of separation of the geoid and the sphereoid. Suffice it to say, however, that the subsequent extension of observations to the mountain so as to include stations situated within the hills, and the adoption of a more probable coefficient of refraction, made the summit some 29,149 ft., but the estimated separation of the geoid and sphereoid, due to deformation caused by local attraction, would reduce this amount, the net result being to assign to the peak a probable height of about 29,050 ft. above mean sea level. There are also certain other corrections which can be estimated theoretically but these are not taken into account in ordinary trigonometrical levelling.

By height above mean sea level is implied the distance of the summit above the geoid immediately beneath it. Accepting this definition, it is not possible to determine accurately the height when access cannot be had to the summit for purposes of observation. Taking into account that there are still doubtful quantities involved, it has been considered best to allow the time honoured figure of 29,002 ft. to stand, anyhow until sufficient data are available to enable a more exact solution of the problem.

It may be asked why so little was known about the highest mountain in the world beyond its position and height, until comparatively recently, considering it was discovered eighty-two years ago. This was, without doubt, due to its great distance from civilisation and above all to the strict political isolation maintained by the two countries, Nepal and Tibet, on the border of which it is situated. The shortest way, some 110 miles, to reach the mountain from India would be through Nepal, but even if the Nepalese Government were willing to permit the passage of its country, the route would be through trackless leach-infested jungles impossible for pack transport. Added to this, the snow line is about 2,000 ft. lower on the south side than on the north, for it is subject to the full force of the monsoon and is probably more deeply eroded and, in consequence, more inaccessible than from the Tibet side. For these reasons successive expeditions have taken the longer route, about 350 miles from Darjeeling via the Chumbi valley, Kampa Dzong and Sheka Dzong, made possible since the Tibetan objection to traversing its territory has been overcome.

This route possessed the advantage of passing through country where pack transport was available, and could be used up to the base camp. Further, it lies at an average elevation of about 14,500 ft., so the long march has a certain beneficial effect in acclimatising the party before the base of operations is reached.

Though the project to climb Mount Everest had been long in the minds of several mountaineers, the first definite move in the matter appears to have been due to Major Rawling and Captain Noel, about the year 1912–13. Both these officers had had experience of Tibetan travel. Then followed the years of the War in which Rawling was killed. The project was revived in 1920, when permission was obtained from the Tibetan Government to approach the mountain through its country. A Committee, consisting of three members each of the Royal Geographical Society and the Alpine Club, was formed to collect funds, select personnel, purchase instruments and equipment and generally to manage the business of an expedition to Everest. The chairman of this Committee was Sir Francis Younghusband.

There have now been three expeditions including the one in 1921, which was of the nature of a reconnaissance. The other two were serious attempts to reach the summit—they were undertaken in the years 1922 and 1924. As already announced, a fourth expedition will leave England early this year.

The expedition of 1921, led by Col. C. K. Howard-Bury, consisted of Dr. A. M. Kellas, C. Raeburn, G. H. L. Mallory, G. H. Bullock, mountaineers, and A. F. R. Wollaston, doctor and naturalist. Since the local topography of the mountain and its neighbourhood was quite unknown, Majors Morshead and Wheeler, of the Survey of India, with three Indian surveyors, and Dr. Heron, of the Indian Geological Survey, joined the expedition in India. Unfortunately, that veteran mountaineer, Dr. Kellas, died at Kampa Dzong on the way out.

The party started from Darjeeling on May 18 and after the long detour through Tibet, already mentioned, reached Tingri, a place about 45 miles north-north-west of Everest, a month later. On June 23, Mallory and Bullock began the exploration of the western and northern sections of Everest. Approach was soon found to be, if not impossible at least very difficult, from the west and north-west. They then turned their attention to the great Rongbuk Glacier which drains the northern slopes of the mountain. It was seen to consist of at least two important branches—one trending away to the west, and the main glacier coming down from the northern face of Everest itself.

As the result of these explorations the following facts were established, that the key of the mountain appeared to be an important saddle, the Chang La (North Col), 22,990 ft., situated at the head of the main Rongbuk Glacier, about 1¾ miles from the summit of Everest, and that it could only be reached with the greatest difficulty from the main glacier. It then became necessary to seek another way of approach to the Chang La. They decided to try what could be done from an easterly direction. They therefore marched round to a new base which, in the meantime, Howard-Bury had established in the Kharta Valley, at the head of which lies the Hlakpa La (22,200 ft.). This point they eventually reached in the face of very adverse weather. It was found to lead to a hitherto unsuspected eastern branch of the Rongbuk glacier, draining into the main valley through a narrow gorge, which had been missed during the first reconnaissance. Mallory, Bullock and Wheeler crossed the East Rongbuk glacier and succeeded in reaching the summit of the Chang La itself on September 24. In doing this they had the most difficult climb, especially for laden men, that had so far been encountered. "Beyond the Col (Chang La) an easy succession of rock and snow slopes could be seen leading to the north-east shoulder (27,390) of Everest."

The weather and the exhaustion of the party prevented any further advance. This closed the season of 1921. The results may be briefly stated. A practical route had been discovered, via the Chang La, which had been reached from the Kharta valley, but there was an easier way by the East Rongbuk glacier which avoided the ascent of the Hlakpa La and consequent descent of about 1,200 ft. in order to reach the foot of the Chang La. The best time for high climbing appeared to be the months of May and early June.

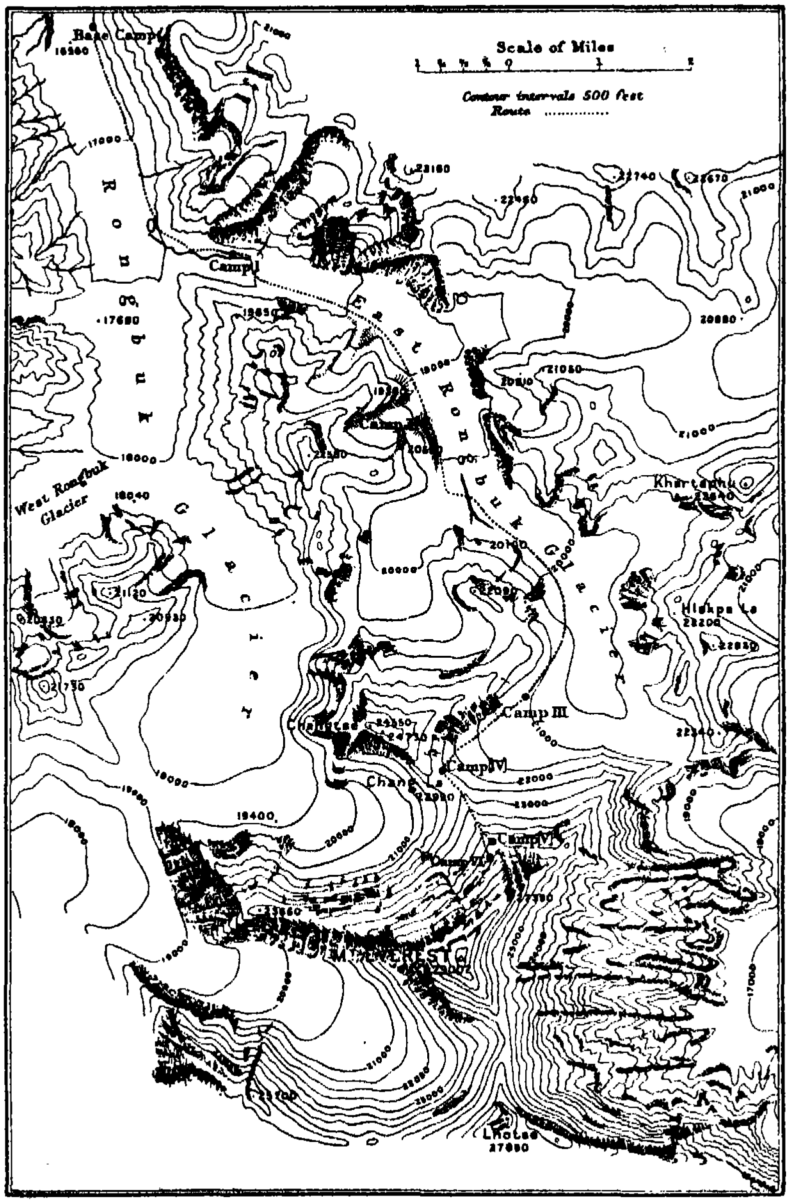

FIG. 1.—Everest and the surrounding country. By courtesy of the Royal Geographical Society

In the course of this reconnaissance, 600 square miles in the immediate neighbourhood of Mt. Everest were mapped photographically on the 1-inch scale, which proved of great use in subsequent expeditions.

A way had now been found to make a real attempt to reach the summit. The expedition of 1922 comprised Brig. Gen. the Hon. C. G. Bruce, as leader, Col. E. L. Strutt, as second-in-command, Mallory, T. H. Somervell, Dr. T. H. Wakefield, Prof. G. I. Finch, Major (now Brigadier) E. F. Norton, mountaineers, Dr. T. G. Longstaff, doctor and naturalist, J. B. L. Noel, photographic and cinema expert. In India the party was joined by the late Lieut.-Col. H. T. Morshead, C. G. Crawford, Capts. Morris and G. Bruce.

One of the questions which the Mount Everest Committee had to consider was the use of oxygen for climbing the last stages of the mountain, which appeared to offer no great difficulty apart from lack of oxygen inseparable from great altitude. It is a matter on which climbers and physiologists are not agreed. Some are in favour of relying on the acclimatisation of those men selected for the final assault. This means remaining for some time at high altitudes under what, at best, must be very trying conditions, where deterioration may set in from the lack of well cooked food and exposure to great cold. The disadvantages of oxygen were the considerable weight of the apparatus, about 30 lb., which the climber himself would have to carry, and the number of porters required to take up the supply of spare cylinders in which the gas is compressed to 120 atmospheres. Then there was the danger of the apparatus going wrong at the critical moment. After taking into consideration all the arguments for and against, "the Committee finally unanimously agreed" to its use.

Profiting by the experience of the previous year, the expedition left Darjeeling on March 26, 1922, following the same route as the year before to Sheka Dzong where they turned south, reaching the spot selected for the Base Camp at the snout of the Rongbuk glacier, 16,560 ft., at the end of April. By May 20 camps were established up to Camp IV as shown on the accompanying sketch map. Camp III at a height of 21,000 ft. at the foot of Chang La on rock, Camp IV on the Chang La, on snow, just under 23,000 ft. What they had now "to aim at was getting two tiny tents carried up the North Face to some niche near the North-East Ridge at a height of 27,000 ft.", that is somewhere above the position of Camp VI on the map, and 2,000 ft. from the top. From such a point it was hoped the final assault on the summit could be successfully made. "So the crux of the situation was the capacity of porters to carry two tents and sleeping bags, provisions and light cooking apparatus for this 27,000 ft. camp" sufficient for four climbers. This arduous work was to be carried out by a specially selected corps of forty Nepalese porters.

The first assault was made on the morning of May 20 from Camp IV, where four climbers—Mallory, Somervell, Norton and Morshead—had slept the night before, but they were only able to reach Camp V, 25,000 ft., and had to spend the night there. The next day was fine and they succeeded in reaching a height of 26,985 ft. just below the north-east shoulder of Everest (marked 27,390 ft. on the map). They were "within one mile of the summit and there appeared to be no serious obstacle in this last remaining lap—only it was more than could be accomplished in one day from a camp at 25,000 ft." They were compelled to turn back on account of the slow progress made and the lateness of the hour. It was between 10 and 11 P.M. before the party reached the shelter of Camp IV on the Chang La. All four were more or less frost bitten during the descent. The worst case was Morshead, who afterwards had to have the top joint of three of his fingers amputated.

Finch, G. Bruce, and the Gurkha Lance-Corporal Tejbir, then made another attempt, this time using oxygen. They were accompanied from Camp IV by twelve porters carrying spare oxygen cylinders and camp gear. The climbers themselves carried the oxygen apparatus weighing about 30 lb. They hoped to pitch a camp at 26,000 ft., but they only succeeded in reaching 25,500 ft. when they were forced by the weather to camp and send the porters back to Chang La. For thirty-six hours the storm lasted, and there was great danger of the whole camp being blown away. On the third day, still using the remaining oxygen, they reached a height of 27,235 ft., about half a mile from the top, when they were compelled to return.

One more attempt was made early in June by Mallory, Somervell and Crawford, but an avalanche, on the steep ascent to the Chang La, carried away seven of the porters, who were killed instantaneously. The monsoon had now arrived and all further attempts for the season were abandoned.

The results of the 1922 expedition were—heights of 27,235 ft. and 26,985 ft. were reached with and without oxygen; it was ascertained that there are no serious physical obstacles between the highest point attained and the summit. Camps were made at 25,000 ft. and 25,500 ft., but it was found that it was not possible from there to reach the top and return in one day. Oxygen was used for the first time, though its efficacy does not appear to have been definitely proved or disproved.

We now come to the third expedition, which was undertaken in 1924. This year Gen. Bruce was again the leader, but owing to illness he was obliged, shortly after the start, to hand over to Col. Norton who had been appointed second-in-command. The other members were Mallory, Somervell, G. Bruce, Odell, Beetham, Hazard, Irvine, Shebbear, Major R. W. G. Hingston, and Noel who was in charge of the photographic equipment which was to contribute so much to the finances of the expedition.

Darjeeling was left on March 25, the old Base Camp at the foot of the Rongbuk glacier being reached on April 29. The three camps in the glacier valley had then to be established and stocked, and the route to Camp IV on the Chang La made practicable for laden porters. This done, Camp V, 25,500 ft., would have to be similarly established and stocked and finally

Camp VI, at 26,500 ft., and possibly another camp (not marked on the map) at about 27,200 ft. "All this had to be done before the actual attempt could be made."

Camps I and II were established and stocked with Tibetan labour, while all above this were worked by the specially enlisted Nepalese porter corps, fifty-two strong. Early in these operations the occurrence of violent winds and snow impeded the work, obliterating the way which had been prepared a short time before. On the night of May 6–7, the thermometer fell to 21½° F. below zero. There were many sick porters at Camp III who had to be sent down to Camp II. In these circumstances it was not easy to keep up the morale of the porter corps. This first attempt got no further than Camp III. It was beaten by the weather and in the end the whole expedition had to retreat to the Base Camp; even this was only carried out with considerable difficulty. "So ended Round One with the mountain."

After a complete reorganisation of the porter corps a fresh start was made on May 17. By May 19 the expedition was in full occupation up to Camp III. The next operation was to tackle the route to Camp IV, which has already been mentioned as the most difficult obstacle. It was here that the seven porters lost their lives in 1922, so the greatest care had to be taken to guard against a similar accident, by finding a way clear of avalanches. This was found by Norton, Mallory and Odell. It proved to be a most exhausting operation, accompanied by several narrow escapes, especially for Mallory, who nearly lost his life by a fall into a crevasse. The establishment of Camp IV was undertaken by Somervell, Hazard and Irvine, using the way marked out by Norton and Mallory. Ropes were fixed at the worst places and a rope ladder was used for negotiating the chimney. Then came the rescue by Norton, Mallory and Somervell of four porters stranded at Camp IV. Incidents like this are most trying and exhausting for members of the climbing party just before they have to make the supreme effort to reach the summit, yet such occurrences cannot be avoided.

The next effort was made by Norton and Somervell with the help of three gallant porters. They pitched a tent at Camp VI, 26,800 ft., and sent the porters back to the Chang La. The night was spent at this height and they slept fairly well. The next morning, June 4, they started at 6.45 for the summit which was about a mile off and 2,200 ft. above them. The going was good, the day perfect. At 27,500 ft. they both began to feel symptoms of distress. Norton felt very cold and had trouble with his eyes; Somervell also was in trouble with his throat and had to stop often and cough. "Now seven, eight or ten complete respirations were necessary for each single step forward." They struggled on, however, to about 28,000 ft., when Somervell could go no further. Norton went on to 28,126 ft., when his progress became very slow. It was then 1 P.M. when he, too, was forced to give up. The cause of their failure was most likely due to want of fitness following the strenuous time they, with other climbers, went through in rescuing the marooned porters, and other exertions which should be avoided if the final climb is to be successful.

The last and final attempt was now to be made. Two climbers without oxygen had failed. It was the turn of others to try with oxygen: Mallory, the experienced mountaineer whose third expedition it was to Everest, and Irvine, the young undergraduate and Oxford blue. On June 7 they set out for Camp VI while Odell was in support at Camp V. On arrival Mallory returned his four porters to Odell and he and Irvine spent the night at Camp VI. In a note which he sent back with the porters to Odell he said, "the weather was perfect but the oxygen apparatus was a nasty load for climbing."

Nothing is known of what happened after this except that Odell saw them at 12.50 P.M. the next day much nearer their camp than he had expected they would be had they started early in the morning. Shortly afterwards the mist shut out the view and Odell saw them no more. That evening Odell returned to Camp IV, where Hazard was. The following day, as the climbers did not return, Odell, with two porters, reascended the mountain intending to visit Camp V and VI, but did not get further than Camp V, where he spent the night. The following morning the weather had changed, a strong and bitter wind was blowing. As he could not persuade the porters to go any higher he sent them back to Camp IV, going on himself alone to Camp VI. This time he took oxygen, though he does not seem to have derived much benefit from it. He eventually reached Camp VI but found no sign of Mallory and Irvine. After searching in vain further up the mountain for a couple of hours, he too was obliged to return. In a storm of gale force he reached Camp IV; it was evidently a forerunner of the approaching monsoon. Here Hazard was awaiting him. Next day they evacuated the Chang La camp. Thus ended the last assault on Mount Everest.

A great adventure deserves a great narrative. The story of Mount Everest has been told in three large volumes splendidly illustrated by the leaders and members of the three expeditions, in which every aspect of the subject has been dealt with in great detail. But this is not all, for these narratives have been admirably summarised and woven into a single story entitled "The Epic of Mount Everest", by Sir Francis Younghusband.

What are the chances of success in 1933? A great deal, in fact almost everything, depends on the weather, and in weather we include wind. The very best laid plans may be wrecked at the last moment by one of those sudden changes which occur in the high Himalaya without warning. Wireless might be used to receive weather reports from the Indian Meteorological Department, but whether they could give indications of the local changes is more than doubtful.

The climbers must be absolutely fit and have had an opportunity of acclimatisation, undisturbed by any incident calling for great exertion on their part, such as having to rescue porters from dangerous positions. Yet such incidents are liable to occur.

The margin between success and failure must always be small—that is what makes it such a great adventure. Many favourable conditions must conspire to take the climbers to the summit; without these, success is doubtful.

We have no information as to the plans of the new expedition but we fancy the same camps will be occupied up to, and including, Camp IV on the Chang La (22,990 ft.) with, perhaps, some form of portable hut at Camp III as has been suggested. Higher up an attempt may probably be made to establish three camps in order to climb the remaining 6,000 ft.

As regards oxygen, since 1924 a much lighter form of apparatus has been constructed, weighing only about 12 lb.* While a high degree of acclimatisation will be aimed at by the climbers selected for the final assault, no doubt the latest form of light oxygen equipment will be provided, so that it can be used if required for the last portions of the ascent. Aptitude for acclimatisation appears to vary with the individual. With some persons, deterioration, due to remaining at high altitudes, may set in before acclimatisation has been fully attained; this has always to be reckoned with. We think, given reasonable luck, Everest will be climbed. If fortune smiles the summit will be reached.

The new expedition will be led by Mr. Hugh Ruttledge, formerly of the Indian Civil Service, who has had a great deal of Himalayan experience. The other members of the expedition are Mr. F. S. Smythe, leader of the successful Kamet expedition, with three of his companions—Capt. Burney, Dr. Raymond Green, and Mr. E. E. Shipton; Mr. Noel Odell, Mr. C. G. Crawford, Mr. Shebbear, members of former Everest expeditions; Messrs. Wyn Harris, J. Longland, G. Wood-Johnson, and Capt. Hugh Boustead, and possibly Dr. W. McLean as second doctor; Mr. L. R. Wager, of the Arctic Air Route Expedition, 1930-31, and Mr. T. Brocklebank.

Scientific Centenaries in 1933

By ENG.-CAPT. EDGAR C. SMITH, O.B.E., R.N.

THE year which has just closed saw the commemoration of the centenaries of many famous men, among whom were Scott, Goethe, Leeuwenhoek, Locke and Warren Hastings. Of especial interest to men of science was the commemoration of the tercentenary of Wren, while the celebration at Cologne of the centenary of Otto attracted considerable attention in the engineering world.

The closing month of the year also saw the commemoration of four other men distinguished as engineers or inventors. On December 7, the American Society of Mechanical Engineers at its annual dinner paid tribute to the memory of John Edson Sweet (1832–1916), a founder of the Society and once professor of engineering at Cornell, and to the memory of Alexander Lyman Holley (1832–1882), a singularly gifted man, whose monument in Washington Square, New York, describes him as "Foremost among those whose genius and energy established in America and improved throughout the world the manufacture of Bessemer steel". Eight days later, on December 15, a ceremony took place at the base of the Eiffel Tower to commemorate the centenary of the birth of its constructor, Gustave Eiffel (1832–1923), while on December 23 various tributes were paid to the memory of Sir Richard Arkwright (1732–1792) who reduced to practice the principle of roller drawing in spinning machines, and was the founder of the factory system of cotton manufacture as we know it to-day. Lecky, the historian, speaking of the wealth which accrued to Great Britain through the cotton mill and the steam engine, and the power this wealth gave the country for carrying on the great French wars, declared that Arkwright and Watt deserved statues beside those of Wellington and Nelson, but so far no monument has ever been erected by his countrymen to Arkwright.

Earlier in the year, at Camborne, Prince George unveiled a statue of the Cornish engineer, Richard Trevithick, the centenary of whose death, falling on April 22 this year, will be commemorated by the engineering world on a scale in keeping with Trevithick's place as a pioneer. Trevithick died at Dartford, Kent, a poor man and for half a century was almost forgotten. The publication of his life by his son in 1872 did much to rescue his achievements from oblivion, and in 1888 a memorial window was erected to him in Westminster Abbey.

The forthcoming celebration is being supported by the leading engineering societies of Great Britain, and the arrangements are in the hands of a committee of which Sir Murdoch Macdonald is chairman. There will be memorial services in Dartford Parish Church and Westminster Abbey, an eminent engineer will deliver an address on Trevithick's work as an inventor, and the committee hopes to be able to erect tablets to Trevithick at his birthplace, Illogan, Cornwall, and also at Pen-y-daren, South Wales, and near Euston Road, London, to record his early attempts to introduce steam locomotion on roads and railways. Trevithick's reputation has never stood higher than it does to-day. He may indeed be proclaimed the father of the high-pressure steam engine.

Many other engineering centenaries also occur this year. A far less well-known inventor who died three months before Trevithick was Frederick König (1774–1833), whose four patents of 1810–14 led to the construction of the flat-bed printing press in which the paper was pressed against the type by a revolving cylinder. A red letter day in the history of printing was November 28, 1814, when the *Times* was first produced on a König machine driven by a steam engine.

Two centuries ago, on February 11, 1733, John Perry died at Spalding at the age of sixty-three years. For many years he was comptroller of maritime works under Peter the Great. He constructed harbour works in Great Britain and as the inscription on his tomb in Spalding Parish Church records, he was "Employed by ye Parliament to stop Dagenham Breach which he Effected and thereby Preserved the Navigation of the River of Thames and Rescued many Private Familys from Ruin".

Engineers born a hundred years ago include Sir Richard Tangye (1833-1906), the best known of the brothers who built up the great Cornwall Works at Birmingham ; Thomas Edwards Vickers (1833–1915), another engineer and captain of industry of world-wide fame ; James Robson (1833–1913), a pioneer of the gas engine ; Henry Wilde (1833–1919), one of the leading inventors of the dynamo and Rudolph Haack (1833–1909) who at Stettin built the first ironclad constructed in Germany, and helped to lay the foundation of the German shipbuilding industry.

Turning to other fields of human endeavour, it is not necessary to stress the interest which is attached to the bicentenary of the birth of Joseph Priestley (1733–1804) who was born at Birstal, Leeds, and died at Northumberland, Pennsylvania. The statues of Priestley at Leeds, Birmingham and Oxford, testify to the esteem in which his memory has been held, and it may be recalled that it was at the celebration on August 1, 1874, of the centenary of his discovery of oxygen, on the piazza of his dwelling-house in Northumberland, that the American Chemical Society was founded, one of many instances of the value of such commemorations. Priestley was one of the few Englishmen elected a foreign associate of the Institute of France, the secretary of which, Cuvier, in his *éloge*, referred to him as "le père de chimie moderne qui ne voulait pas reconnaître sa fille".

Among Priestley's intimate friends was the geologist and chemist, Richard Kirwan (1733–1812), who, like Priestley, received the Copley medal of the Royal Society. Kirwan was in correspondence with many of the leading savants of Europe, his London house was the meeting-place of the learned and after he returned to his native country, he became president of the Royal Irish Academy.

The year 1733 also saw the birth of Jean Charles Borda (1733–1799), the eminent French mathematician and astronomer ; of Dr. Thomas Hornsby (1733–1810), the successor of Bradley as Savilian professor of astronomy at Oxford and the first Radcliffe Observer, and of the famous German traveller, Carsten Niebuhr (1733–1815), the pupil and friend of the astronomer, Tobias Mayer.

Somewhat later than these eighteenth century worthies came Joseph Nicephore Niepce (1765–1833), the French chemist, whose statue at Chalons recalls his achievement of obtaining sun prints on metal plates ; Thomas Allan (1777–1833), the Edinburgh mineralogist ; Adrien Marie Legendre (1752–1833), the French mathematician, writer of many works and the contemporary of Lagrange and Laplace. Legendre's "Elements of Geometry" was translated into English by Thomas Carlyle.

To the names of these three men who died in 1833 may be added that of Dr. William Babington (1756–1833), whose statue in St. Paul's Cathedral is regarded as a fine example of portraiture in marble. Babington was physician for many years to Guy's Hospital, and it was at his house that the meetings took place which led to the foundation of the Geological Society. Active to the last, when seventy-six years of age, he presided over the Priestley centenary festival on March 26, 1833, but died of influenza three days later. He is buried in St. Mary Aldermanbury in the City.

Coming nearer our own times, it is but natural that with increase of opportunity, the lists of men who make notable contributions to discovery and progress should grow longer. "Life," said Emerson, "is girt round with a zodiac of sciences, the contributions of men who have perished to add their point of light to our sky. These road makers on every hand enrich us." To this ever-increasing group of men belong many born in 1833, among them Sir Henry Roscoe (1833–1915) ; the German mathematician, Rudolph Clebsch (1833–1872) ; and the meteorologist, Robert Henry Scott (1833–1916), the successor of FitzRoy at the Meteorological Office. On April 15 was born Maurice Loewy (1833–1907), the constructor of the equatorial coudé and the successor of Tisserand as director of the Paris Observatory ; on May 5, Ferdinand, Baron von Richthofen (1833–1905), the geologist and geographer ; on March 16, Hilary Bauerman (1833–1909), the metallurgist and benefactor of the Iron and Steel Institute and the Royal School of Mines ; and on June 29, Peter Waage (1833–1900), the distinguished Norwegian chemist, student of Bunsen, successor of Strecker and collaborator with Guldberg.

Then, too, on October 15 and October 21, 1833, respectively, occurred the births of Frederick Guthrie (1833–1886), through whose efforts the Physical Society of London was founded, and of Alfred Bernhard Nobel (1833–1896), the Swedish engineer, chemist and inventor of explosives, by whose will of November 27, 1895, the bulk of his great fortune was used for founding the famous Nobel prizes for physics, chemistry, medicine, literature and peace.

Empire Broadcasting

IN the field of radio communication, the last few weeks of the year 1932 were conspicuous for the inauguration of a regular broadcasting service between Great Britain and the various portions of the British Empire. The developments which took place in this connexion during 1932 are somewhat striking, and they are recorded in some detail in the B.B.C. Year Book for 1933. From the previous edition of this Year Book, it appeared that little progress was likely in connexion with the Empire broadcasting scheme drawn up by the British Broadcasting Corporation owing to lack of support by the Colonial and Imperial Conferences of 1930, and the responsible authorities in the overseas countries concerned. In November 1931, however, the B.B.C. announced its intention of developing the Empire broadcasting scheme on its own initiative, and the rapid progress made during the ensuing twelve months is illustrated by the fact that the regular service from the new station erected at Daventry for the purpose began on December 19.

As an aid in the development of this new broadcasting service, the B.B.C. had the benefit of about five years' experience with an experimental short wave station erected at the Marconi Company's works at Chelmsford. Owing to the fact that the distances from Great Britain to the various Dominions and Colonies are in the range 2,000–13,000 miles, it is necessary to make use of the short wave-length band of approximately 12–60 metres for radio communication. The Chelmsford station operated on a wave-length of 25 metres, and enabled a large amount of technical data to be obtained in connexion with short wave broadcasting. A little consideration of the matter will show, however, that one transmitting station working on a single wave-length cannot provide a satisfactory Empire broadcasting service. In the first place, account must be taken of the wide differences in local time in the various countries concerned, and it is obvious that the broadcast reception must be possible in general during the leisure hours of the inhabitants of those countries. Secondly, as a result of experience, not only in broadcasting but also with ordinary telephonic and telegraphic radio communication on short waves, it is known that the choice of the best wave-length varies with the distance to be covered, and whether the portion of the earth over which the communication takes place is in sunlight or darkness. Following on the latter condition, it is frequently found that diurnal and seasonal variations in the ionosphere, without which long-distance short wave communication would apparently not be possible, make it necessary to have a choice of at least two wave-lengths in order to maintain regular communication between two fixed points. Lastly, a directive antenna system at either or both ends of the communication link, makes such a vast improvement in general efficiency that the arrangement is always employed where possible in commercial short wave communication.

Based upon the considerations outlined above, the British Empire has been divided up into five zones and the new station at Daventry is designed to supply a direct broadcasting service to listeners in each zone, a two-hour programme being given daily between 6 P.M. and midnight local time, with the hours 8–10 P.M. as a focus wherever possible. For each zone a separate antenna array has been erected at Daventry, each array being so oriented as to give a not too highly concentrated beam of radiation in the desired direction. In the case of the first array, for Australasia, the transmission is limited to a single wave-length of 25·5 metres, but the radiator and reflector units of the array are reversible so that the waves can be transmitted around the earth in either direction. In the case of the other four zones, two or three wave-lengths are available as required. The approximate constitution of these zones, with the wave-lengths available, and the periods in G.M.T. at which the transmissions take place in Great Britain are given in the following table:

Zone.	Countries.	Wave-lengths (metres).	Approximate programme period (G.M.T.).
1	Australasia, including New Zealand, Borneo, New Guinea and the Pacific Islands	25·5	9.30–11.30 A.M.
2	India, with Burma and the Federated Malay States..	17, 25 and 32	2.30– 4.30 P.M.
3	South Africa, with East Africa, Palestine, Sudan and Somaliland	14 and 32	6.0 – 8.0 P.M.
4	West Africa, Nigeria and Gold Coast, with Tristan da Cunha and Falkland Islands	32 and 48	8.0 –10.0 P.M.
5	Canada, Newfoundland and West Indies	19, 32 and 48	1.0 – 3.0 A.M.

In addition to the directional antenna arrays, six omnidirectional aerials have been provided and these will be used for transmitting any special programmes which it may be desired to receive at any hour in any part of the world.

These arrays and aerials are supplied by feeders or transmission lines from two transmitters housed in the new station building at Daventry. Each of these transmitters is of modern design and construction, and comprises a crystal-controlled master oscillator followed by the necessary frequency multiplying, modulating and energy amplifying stages: these terminate in a final amplifier which consists of four 15 kw. valves connected in push-pull arrangement, the output circuits of which are coupled to the aerial feeder.

The programme supplied through this station will comprise items largely of an original or topical nature, having entertainment or news interest of a type not normally obtainable in the countries where reception takes place. Owing to the difficulties of arranging repeat performances, particularly at the more inconvenient times shown in the above table, the B.B.C. will make extensive use of modern electrical methods of programme recording for use in the transmitters. As an example of the use of the station, reference may be made to the occasion of the broadcasting of the King's Christmas message on December 25 last, when the vision of Sir Ambrose Fleming and other pioneers of radio communication, of a single human voice addressing listeners over the whole surface of the earth, was realised. In addition to being transmitted by all the B.B.C. stations serving Great Britain, it was sent through the two Empire transmitters at Daventry. One of these was connected to the Indian zone array, for which zone the transmission took place at the normal time. The other short wave transmitter was operated on a wave-length of about 20 metres, and supplied an omnidirectional aerial, so as to broadcast so far as possible in all directions. In addition, the programme was recorded by Blattnerphone and used for re-transmission in the various zone programmes later in the day.

In addition to the direct reception from Daventry on listeners' private receiving sets, it is likely that the broadcasting authorities in the Dominions will arrange for the relaying of some programmes through their local stations operating on medium wave-lengths. From the point of view of the B.B.C., the whole Empire service will be experimental for a period of about six months, during which arrangements will be made to collect reports of reception from selected listeners in all parts of the Empire.

News and Views

New Year Honours

THE New Year Honours List includes the following names of scientific workers and others associated with scientific work: *Baron:* Sir Thomas Horder, Bt., senior physician to St. Bartholomew's Hospital. *Knight of the Thistle:* The Right Honourable Sir Herbert Maxwell, Bt., chairman of the Royal Commission on Scottish Historical Monuments, president of the Society of Antiquaries of Scotland, 1900–13. *K.C.B.:* Sir Frederick Leith-Ross, chief economic adviser to His Majesty's Government. *K.C.I.E.:* Major-General J. W. D. Megaw, Director-General of the Indian Medical Service. *K.C.V.O.:* Mr. F. J. Willans, surgeon apothecary to H.M. Household at Sandringham. *Knights:* Mr. C. A. Cochrane, chairman of the Council of Armstrong College, University of Durham. Mr. H. H. Dalrymple-Hay, consulting engineer, for his inventions and services in connexion with the construction of tube railways. Prof. F. T. G. Hobday, Principal and Dean of the Royal Veterinary College. Mr. A. J. C. Huddleston, lately economic adviser to the Sudan Government. Mr. J. L. McKelvey, for services to surgery in the Commonwealth of Australia. Mr. E. R. D. Maclagan, Director and Secretary, Victoria and Albert Museum. Mr. W. Perry, president of the Royal Agricultural Society, New Zealand. Mr. R. S. Rait, Principal and Vice-Chancellor of the University of Glasgow since 1929. *C.H.:* Rev. John Scott Lidgett, president of the Methodist Church, Vice-Chancellor of the University of London in 1930–31 and 1931–32. *C.M.G.:* Dr. J. J. C. Bradfield, Government engineer, Sydney Harbour Bridge, State of New South Wales. Prof. D. B. Copland, professor of commerce, University of Melbourne. Mr. L. Ennis, constructing engineer for Messrs. Dorman, Long and Co., Sydney Harbour Bridge, New South Wales. Mr. W. B. Johnson, director of Medical and Sanitary Service, Nigeria. Mr. W. J. U. Woolcock, formerly general manager of the Association of British Chemical Manufacturers, chairman of the Committee of Non-official Advisers associated with the industrial advisers of the United Kingdom delegation at the Ottawa Conference. *C.I.E.:* Major-Gen. W. C. H. Forster, Surgeon-General with the Government of Bombay. Lieut.-Col. R. B. Seymour Sewell, director of the Zoological Survey of India. Mr. C. G. Trevor, chief conservator of forests, Punjab and North-West Frontier Province. Col. J. N. Walker, director of the Medical Department and Sanitary Commissioner, his Exalted Highness the Nizam's Government, Hyderabad, Deccan. *C.B.E.:* Mrs. Alice Baker, one of the founders of the Thomas Baker, Alice Baker, and Eleanor Shaw Medical Research Institute, Melbourne, Commonwealth of Australia. Dr. F. H. A. Marshall, reader in agricultural physiology in the University of Cambridge. Dr. S. W. Smith, chief assayer, Royal Mint, and president of the Institute of Mining and Metallurgy. Dr. H. A. Tempany, director of agriculture, Straits Settlements and Federated Malay States. Prof. H. E. Whitfeld, Vice-Chancellor of the University, State of Western Australia. *O.B.E.:* Dr. J. T. Bradley, chief medical officer, Seychelles. Mr. A. V. Elsden, War Department chemist, Royal Arsenal, Woolwich. Mr. A. McCallum, senior inspector for agricultural education, Department of Agriculture for Scotland. Mitharam Pribhdas Mathrani, executive engineer, Left Works Division, Lloyd Barrage Circle, Sukkur, Bombay. Dr. S. A. Neave, assistant director, Imperial Institute of Entomology. Mr. J. Smith, director of animal health and acting secretary for agriculture, Northern Rhodesia. Mr. H. W. O. Taylor, executive engineer, Right Works Division, Lloyd Barrage Circle, Sukkur, Bombay. Mr. R. S. Taylor, principal medical officer, Somaliland Protectorate. *M.B.E.:* Mr. J. Coelho, assistant Crown surveyor and assistant engineer, Public Works Department, Gibraltar. Mr. W. M. Schutte, agricultural engineer to the Government of Bombay. Mr. H. N. Williams, assistant engineer, Irrigation Department, Iraq.

Calendar of Nature Topics

FOR the past nine years calendars have been published in our columns recording week by week notes of historic interest relating to people and institutions, discoveries and inventions, customs, festivals, geographical exploration and other matters appropriate to a scientific "Book of Days". We began in 1924 with "Early Science at the Royal Society", and during last year appeared a "Calendar of Geographical Exploration", which was contributed by Miss R. M. Fleming and most admirably fulfilled its purpose. With this issue begins an annual cycle of a different kind relating to natural history in a wide sense, as was understood, for example, by Gilbert White in the notes and letters which make up his famous "Natural History of Selborne". Prof. James Ritchie, Regius professor of natural history in the University of Aberdeen, will be chiefly responsible for the weekly notes in this "Calendar of Nature Topics", and Dr. C. E. P. Brooks will deal with meteorological events of topical interest. In addition, we hope to receive occasional notes on such subjects as agriculture, botany, marine biology, fisheries and similar branches of pure and applied natural history from other contributors.

It is not intended that this year's Calendar shall be of the usual type, recording aspects of Nature or country life week by week in Great Britain, but that it shall take a much wider outlook. The main idea will be to bring together, in chronological sequence throughout the year, observations and conclusions representing ascertained knowledge to-day on the subjects of the notes; and the range of the natural occurrences or phenomena may be that of the whole world. It is unlikely, therefore, that there will be any lack of suitable material; nevertheless, suggestions of topics of interest for inclusion in this new Calendar, or short notes which might be used, would be helpful and should be sent to Prof. Ritchie at the University of Aberdeen. It need scarcely be said that any such communications should be sent well in advance of the dates to which they refer.

Centenary of Legendre, 1752-1833

The centenary occurs on January 10 of the death of the eminent French mathematician, Adrien Marie Legendre, whose labours over a period of sixty years were contemporary with those of Lagrange and Laplace, with whom he formed part of "that constellation of mathematical talent of which Paris was for more than two generations the main centre". Legendre was eighty years of age when he died, having been born at Toulouse on September 18, 1752. He was educated at the Collège Mazarin and at the age of twenty-five became a professor at the military school in Paris. He published his first important memoir, on attractions, in 1783, and in that year he was elected a member of the Paris Academy of Sciences. Four years later, with Cassini and Mechain, he was appointed to conduct the geodetical operations for connecting the Observatories of Paris and Greenwich. Through this he visited London, and was made a foreign member of the Royal Society. Unlike many of his contemporaries, he passed through the Revolution unscathed and by his writings and his work on commissions continued to add to his reputation. In 1795 he became a member of the staff of the famous Ecole Normale. His chief works were his "Géométrie" (1794), which was translated into English by Thomas Carlyle, his "Théorie des Nombres" (1798), "Calcul Intégral" (1811-1826) and "Fonctions Elliptiques" (1825-26). A few weeks before his death he added to the last of these another volume, which contained some of the researches of the younger mathematicians, Abel and Jacobi, the value of whose work Legendre quickly recognised. Among the best-known pupils of Legendre were Cauchy and Arago. The death of Legendre took place at his house at Auteuil.

Sir Henry Roscoe, 1833-1915

Among those whose efforts aroused Great Britain to a realisation of the value of scientific education few did more than Sir Henry Enfield Roscoe, whose birth took place in London on January 7, 1833, a century ago. The son of a judge and a grandson of William Roscoe the historian, he got his second christian name from a great-grandfather, Dr. Enfield, a colleague of Priestley's at Warrington. He was sent first to Liverpool High School and afterwards to University College, London, where he came under the influence of Graham and Williamson. Later, he spent some time under Bunsen, working in the historic old laboratory at Heidelberg where "beneath the stone floor at our feet slept the dead monks, and on their tombstones we threw our waste precipitates". Returning from Germany, Roscoe at the age of twenty-four years was appointed to succeed Frankland at Owens College, Manchester, a position he held with conspicuous success for thirty years. He was one of the foremost in engendering a spirit of research and many of his students afterwards rose to high rank. His collaboration with Dittmar, Harden and Schorlemmer, the first professor of organic chemistry in Great Britain, led to the publication of many notable works some of which are still sought after. One of his achievements as an experimentalist was the isolation for the first time of vanadium. He was elected a fellow of the Royal Society in 1863 and awarded a Royal medal in 1874; he served as president of the Society of Chemical Industry in 1881, and as president of the Chemical Society in 1882. He was elected member of parliament for South Manchester in 1885; in 1887, the year in which he retired from Owens College, he was president of the British Association. He was a member of various Royal commissions, and from 1896 until 1902 was Vice-Chancellor of the University of London. His eightieth birthday was marked by the presentation of his bust to the Chemical Society. He died on December 18, 1915, at Woodcote Lodge, West Horsley, Surrey, and was buried four days later in Brookwood Cemetery.

North Atlantic Gale

The last day of the old year and the first few days of the new have proved remarkably tempestuous on the North Atlantic. During the near approach to Ireland on December 31 of an exceptionally intense cyclonic depression, a destructive gale occurred in Ireland. At Valentia Observatory the pressure tube anemograph registered a gust of 96 miles an hour, which is the highest gust recorded there for at least sixteen years. Barometric readings in Iceland were unusually low during the three first days of 1933. On January 3, pressure at sea-level was less than 928 millibars (27·4 in.) near the centre of a depression lying off the south-west coast of Iceland, but it is not possible to say by how much it fell below that value. That depression was certainly among the deepest of which we have any record since daily synoptic weather charts of the North Atlantic were first begun. On those prepared and published by the Danish and German Admiralties, there is only one depression which looks to have had such a low reading, that of February 24, 1903, which had been preceded five days earlier by another only slightly less intense.

Earthquake in South-East Africa

THE strong earthquake that occurred shortly after 8.30 A.M. on December 31 in south-east Africa possesses some interest as it visited a region in which destructive shocks are almost or quite unknown. Its epicentre seems to have been in Zululand, for damage to buildings was caused at Eshowe and other places. The shock was felt all over Zululand and Natal, in various parts of the Transvaal and the Free State, and from Lorenzo Marquez on the north to the Transkei on the south. Its disturbed area must therefore have contained about a quarter of a million square miles, which is more than that shaken by the great Japanese earthquake of 1923.

Ancient Man in Palestine

IT is reported that Miss Dorothy Garrod, director of the Joint Expedition of the School of Archæology in Palestine and the American School of Prehistoric Research, has discovered further remains of Palestine man. A massive and powerful lower jaw has been found in the cave of the Oven at the foot of Mount Carmel. In an announcement of the discovery by Dr. Grant MacCurdy, of Yale University, director of the American School of Prehistoric Research, it is stated that the character of the newly discovered jaw fully conforms to the view, based upon the evidence previously discovered in the caves of Mount Carmel, that Palestine man, while presenting Neanderthaloid characters, is of a distinct type. It is also announced that a cap or veil made of dentalia shells has been discovered in an adjacent cave. It will be remembered that in the course of the excavations of 1931, Miss Garrod found a cap of dentalia shells still attached to a skull from a mesolithic series in one of the Mugharet el-Wad caves.

Cave Paintings in the Pyrenees

FURTHER details of an interesting discovery of the prehistoric painting of a horse in a cave in the Pyrenees, briefly announced some weeks ago, are now supplied by Science Service, Washington D.C. The cave, to be known as La Grotte de la Bastide, is situated near the village of La Bastide, Hautes Pyrénées, and was discovered by M. Norbert Casterat, pupil of Count Bégouen. At the entrance of the cave were intact Magdalenian hearths, and on the walls were a number of engravings and polychrome paintings, including human figures, and as the central object, a polychrome painting of a horse. The horse is described as 'superb' and is an artistic production comparable with the famous horse of the Altamira cave at Santander. The figure is more than six feet long, and is executed in red with black muzzle. The mane is erect; the eye, ear and nostril being delicately engraved. High lights are indicated on shoulders, stomach and flanks. Judging from this description, the painting would appear in every way to be an exceptionally fine example of cave art.

Lightning Investigation

MR. W. H. F. TREDRE, honorary technical secretary of the Educational Section of the South African Institute of Electrical Engineers, Kelvin House, 100 Fox Street, Johannesburg, has favoured us with some interesting particulars relating to the organisation which has been established for the study of lightning in South Africa. The movement was initiated by Mr. T. P. Pask in a paper read before the South African Institute of Electrical Engineers in April 1930; as a result a committee was formed under the chairmanship of Mr. Pask. The present organisation consists of a main committee and three subsidiary committees dealing with each of the subjects research, statistics and education. With regard to the research, the chairman is Dr. B. F. J. Schonland, of Capetown—the scope of the work it is proposed to undertake includes the collection of photographs of lightning strokes and their effects taken by means of revolving lenses of the type suggested by Prof. Boys, of klydonograms and cathode ray oscillograms of lightning waves, point discharge work, etc. The activities of the statistical section may be illustrated by the fact that there are 3,500 observers throughout the Union who are collaborating by making notes on the history of storms. These observers are working under the supervision of Mr. G. W. Cox, acting chief meteorologist of the Union. The educational section will disseminate information on protective measures through the medium of the Press, schools, pamphlets, etc. During the 1933 session it has been arranged for certain of the investigators to read papers on the subjects of their work before the South African Institute of Electrical Engineers. It is anticipated that interesting results will be obtained at the end of the present lightning season.

Electrification of Railways in Britain

IN a paper by F. Lydall to the Institute of Transport read on December 12, the electrification of railways is considered under two headings, 'suburban passenger' and the 'general' electrification usually referred to as main line electrification. The main characteristics of the former type of traction are rapid acceleration and increased terminal capacity due to the elimination of locomotives and the ability of the trains to run equally well in either direction. The practically universal adoption of the multiple unit system for suburban traffic, where several coaches throughout the train are provided with motors, proves that the flexibility this gives to the make-up of the train is of great value in practice. It is usual to divide the trains into units, each unit consisting of one motor coach and several trailer coaches. In the new express service from London to Brighton, the trains are made up of six or twelve coaches, two or four of which are motor coaches, each being equipped with four 225 horse power motors. Over a new portion of an American railway where the stops are 1·55 miles apart, the average speed including stops is 31 miles per hour; on another portion of the line where the stops are 2·9 miles apart the average speed is 40 miles per hour. The increase over the speed of steam trains in Great Britain is about 50 per cent. This speed could be easily increased; it is merely a question of cost. Mr. Lydall considers that on main lines it would be found advisable to work not less than one third of the passenger train mileage by multiple unit stock. By electrification the average speed of passenger trains in Britain could be raised by 25 per cent. The combination of greater comfort, higher speed, and more frequent service would attract many more passengers, and the latter two would also enable the railways to recover much of their goods traffic which at present goes by road transport.

Motor Car Lights on the Road

WHEN motor cars pass each other at night time, there is often a blinding glare in the drivers' eyes. We learn from *Science Service* that, in the United States, the Bureau of Standards has been conducting an extended research on head-lights to discover how glare can be avoided. Dr. Dickinson of the Bureau of Standards concludes that the most important difficulty in obtaining safe head-lighting is the great disparity in brightness between beams from different lamps. One head-light beam is frequently ten times as intense as another. The driver with the dim lights experiences an almost complete lack of visibility when his car plunges into the bright light of the approaching car. Dr. Dickinson suggests that if the lights were kept so that no head-lamp was more than two or three times brighter than another, most of the glare problem would be solved. Most drivers rely on what they can see of the curb rather than what they see of the oncoming car. Hence the light is increased for a hundred feet in front of the car and the beam is widespread horizontally and slightly depressed. Few motorists realise that it is more dangerous to pass a car that is standing still than one that is running fairly fast. A driver in judging whether the road is clear relies on what he has seen during the past few seconds by the light of the oncoming car. But the road immediately at the back of a car at rest is not illuminated in this way and so danger may lurk there unseen. Exposed lights along the roads sometimes increase the risks of night driving. They often make objects almost invisible which could easily be seen by the head-lights alone.

Early Days of the Turbine

IN his inaugural address as chairman of the North-Eastern Centre of the Institution of Electrical Engineers, Mr. C. Turnbull gave interesting reminiscences of some of the initial difficulties Sir Charles Parsons met in perfecting the steam turbine. His experiments with early forms of the turbine were in entirely new and unexplored regions of engineering. Everything had to be found out. Steel discs were run under stresses that no one could calculate and no one knew whether they were safe or not. The early high-speed turbines ran at 4,800 revolutions a minute. But thanks to the wonderful care always taken at Parsons's works, accidents were very rare. When driving dynamos at high speeds, the armature reaction caused great difficulty. Several solutions were adopted for turbo-alternators. In one way the brushes were moved automatically with the load by steam pressure and the variation of the strength of the field was counteracted by special windings. A further difficulty was that owing to the springing of the shaft, the connexions between the armature and the commutator used to give trouble. This was overcome by the use of flexible connectors, a device first proposed by Parsons. It has proved of the greatest value. Details are given of the famous *Turbinia* and the heartbreaking experiences with the destroyers *Viper* and *Cobra*. Mr. Turnbull tells how Parsons refused to give up and how his perseverance ultimately led to success. Another great invention that came from Parsons's works was the invention of means for balancing high-speed machinery. The early days of the steam turbine were hard days and the labour expended seemed to lead to nothing. At one time it was doubtful if the steam turbine would ever become practical. The story of Parsons's life should prove very encouraging to young and old inventors.

The New Helm or Steering Orders

THROUGH the work of the International Safety at Sea and Load Line Convention, and the passing of the Merchant Shipping Act, 1932, and in accordance with the subsequent instructions of the Board of Trade, on January 1 the 'direct' system of helm orders came into use on all British vessels. For centuries the order to "Starboard the helm" or "Port the helm" has caused the ship's head to go in the opposite direction, the practice having come down through the centuries when tillers were in use. Under the new regulations the order "Starboard" will be given, when it is intended that the wheel, the rudder blade and the head of the ship should go to starboard, and the order "Port" will be given when it is intended that the wheel, the rudder blade and the ship's head should go to port. Though it is expected that little difficulty will be experienced in changing over from the 'indirect' system to the 'direct' system, for a time the orders will be given in the words "Wheel to Starboard" and "Wheel to Port", thus enabling the helmsman to adapt himself gradually to the new system. Like most innovations of the kind, the change in established practice has not been introduced without considerable criticism and opposition, but it is probable that in a very short time it will be regarded as an eminently sensible and desirable alteration.

Research at the Port Erin Biological Station

A SEPARATE report on the work of the Port Erin Biological Station has been discontinued and a survey of the research done is now published in the "Report for 1931 (No. 40) on the Lancashire Sea-Fisheries Laboratory at the University of Liverpool and the Annual Report of the Marine Biological Station (No. 45) at Port Erin, Isle of Man", 1932, edited by the late Prof. James Johnstone and Dr. R. J. Daniel. In this report a large amount of original work is also published. This covers a wide field and deals with the abdominal musculature of Crustacea, herring investigations, hydrography and the fauna and flora of the Isle of Man. The Port Erin Station has recently (1931–32) had a new laboratory added, fully equipped for practical teaching and with about thirty work places. New engines and pumps have been installed. The plaice hatchery and lobster culture are still continued. Besides liberating lobsterlings hatched and reared in the laboratory, a number were placed singly in glass rearing jars and fed on crab, boiled and ground to a fine meal. Nearly half of the number survived and cast their shells four or five times, making eight or nine casts between the period of hatching and the end of the first year. The newly hatched young are fed on fresh plankton; after the fourth moult (lobsterling) they are fed on crushed crab, small pieces of fish being added after the fifth month. These interesting experiments are to be continued on a larger scale next year. Dr. R. J. Daniel has completed his comparative work on the abdominal muscles of the Malacostraca and has drawn up an elaborate phylogenetic table to express the relationships that exist between the main ventral system of musculature.

A New Source of Rubber

IN order to avoid the necessity of importing rubber from tropical countries, the Soviet Government has organised investigations of native plants likely to contain this valuable product in their latex. Amongst various plants studied, several species of *Chondrilla* (Compositæ) occurring mainly in the southern sandy regions, proved to be very promising and their cultivation is being carried out on an extensive scale. Green parts of the plant are cut and rubber prepared from the latex. The quantities obtained must be rather small, since only up to 2 per cent of the green mass represents rubber. Recently, however, it was found that certain insects feeding on roots of *Chondrilla* can be utilised for extracting rubber from the latex (Veltischev and Luppova, *Priroda*, No. 10, 1932). One of these is a caterpillar of a pyralid moth, *Bradyrrhoa gilveolella* Tr., which feeds on the roots and constructs round its body a tube formed of condensed latex and sand grains. Up to thirty and more such tubes can be found on the roots of a single plant, and the tubes contain 9–17 per cent of rubber. Another useful insect is the larva of a buprestid beetle, *Sphenoptera foveola* Gebl., which also feeds on roots of *Chondrilla* and causes a large outflow of latex solidifying round the root. These swellings contain up to 4 per cent of rubber. Neither insect produces any serious effect on the infested plant, and healthy plants can be infested artificially in order to increase their productivity. Experiments are being made to test the practical and economic side of this method of obtaining rubber.

Cultivation of Green Crops

BULLETIN No. 53 of the Ministry of Agriculture and Fisheries ("Cabbages and Related Green Crops". London: H.M. Stationery Office, Price 9d.) has recently been published. It traces the botanical origin of the various green crops, and deals in detail with the soils, rotation, manuring, harvesting and marketing most suitable for cabbages, savoys, Brussels sprouts, cauliflowers and several miscellaneous green crops. A very interesting section deals with the saving of seed in the counties the climate of which is most suitable for this purpose. Pests and diseases are not mentioned in the present pamphlet, since they have been described very fully in other publications of the Ministry.

Astrolabes and Their History

ASTROLABES are not as generally available for study in the museums of the world as their scientific importance and artistic qualities would merit, but all who may desire to become better acquainted with this instrument in its various forms are now given the opportunity. Subscribers are invited for a comprehensive work, entitled "The Astrolabes of the World", based upon the series of instruments in the Lewis Evans Collection in the Old Ashmolean Museum at Oxford, in the Science Museum at South Kensington, and in several other public and private collections in Europe and America. The early Greek treatise on the astrolabe, by Philopon, and the Syriac treatise by Sabokt—both dating from the seventh century—will appear in English for the first time. Illustrations are given of Chaucer's astrolabe, now clearly identified by the character of the rete as depicted in MSS. and many instruments contemporary with Columbus and Drake, are figured. The subject is of fundamental importance to all students of the history of astronomy, geography and surveying, and indeed to the history of science generally, for it may truly be said that the astrolabe kept alight the torch of the scientific method of observation and of computation of results, in many countries, and through many dark ages, when larger instruments and well equipped observatories did not exist. It is hoped that the principal reference libraries may obtain copies of this monumental work, which it is proposed to issue in two quarto volumes, containing more than 600 pages and 155 plates, of which 12 are in collotype, and 216 text figures. The price to subscribers is ten guineas. Subscription forms may be obtained from Dr. R. T. Gunther, Curator of the Lewis Evans Collection, in the Old Ashmolean, Broad Street, Oxford.

World Power Conference

The preparatory work of the organising committee at Stockholm of the next World Power Conference, which will take place in 1933 in Scandinavia, is proceeding steadily. The first plenary World Power Conference was held in London in 1924, the next in Berlin in 1930. There have also been sectional meetings with special programmes, for example, at Basel in 1926 and London in 1928. The Scandinavian Conference will be such a special meeting, dealing with the energy problems of large industry and transport. Participation and collaboration of fifteen countries outside Scandinavia is assured and more than 170 reports are announced. Some forty reports to be published at the meeting deal with problems of energy supply in large-scale industry, such as combined power and heat supply, the rôle of large-scale industry in national power schemes, etc. Many of the technical papers deal with the problems of long distance gas transmission, while other papers are devoted to more special power problems concerning the iron and steel industry, pulp and paper, and cement, sugar, textile and other steam heat consuming industries. Energy questions of transport provide the subjects for 62 reports; railway and marine transport, the peculiarities of city and suburban traffic are to be discussed with due emphasis on the new aspects which have been introduced by electric traction and Diesel engines.

Medical Research in South Africa

The annual report of the South African Institute for Medical Research, by the director, Sir Spencer Lister, summarises the work of the Institute during 1931. Methods of dust estimation and studies on underground humidity in the air of the Witwatersrand mines have been pursued. The pneumonia attacking the native labourers in the copper mines of Northern Rhodesia has been investigated, and has been found to be caused by the *Streptococcus pyogenes* and other organisms, but rarely by the pneumococcus. This change of type of the organisms causing pneumonia has also been found in the Kimberley diamond mines. Much experimental work has been done on cancer, and Dr. des Ligneris has found that a micro-organism, *Salmonella gallinarum* of fowl typhoid, if cultivated in the tumour filtrate of the Rous fowl sarcoma for several generations, appears to have the power on inoculation of prolonging the life of fowls with the Rous sarcoma by about fifteen per cent.

The March of Influenza

According to a report of Science Service, Washington, D.C., a considerable outbreak of influenza is in progress in several States of the Union, particularly in the south and west, the United States Public Health Service reporting 14,291 cases during the week ended December 3. In Great Britain outbreaks are reported in Southampton and Birmingham, and during the week ended December 17 in 117 great towns, including London, of England and Wales, 85 deaths from influenza were certified. In the same week Glasgow reported 28 deaths from this disease.

Announcements

The following have been elected officers of the Royal Society of South Africa for 1933: *President:* Dr. W. A. Rogers; *Treasurer:* Dr. L. Crawford; *General Secretary:* Dr. B. F. J. Schonland.

The Royal Society Mond Laboratory at Cambridge will be opened by the Chancellor of the University, the Right Hon. Stanley Baldwin, on February 3. It will be recalled that the hydrogen liquefaction plant of the Laboratory was described in Nature for February 13, 1932, p. 224.

We regret to learn of the death on December 25 of Prof. Paolo Enriques, professor of zoology in the University of Padua and president of the last International Congress of Zoology; he was just starting for Naples to pursue his researches in the Zoological Station. Also of Prof. James Johnstone, professor of oceanography in the University of Liverpool, formerly director of the Marine Biological Station, Port Erin, aged sixty-three years.

Catalogue No. 552 of Messrs. Francis Edwards Ltd., High Street, Marylebone, W.1, includes a miscellaneous collection of books, autographs and manuscripts, falling under such headings as Africa, America, Economics, Geography, History, First Editions, Scripture, Shakespeare and the like. There are also special series such as the publications of the Hakluyt Society and books from special presses such as the Kelmscott and Doves Presses. Among the books listed under Africa to be noted especially are Angas "The Kaffirs" with the coloured lithograph plates (£21) and a copy of the 1727 folio edition in Dutch of Peter Kolben's famous and invaluable account of the Cape of Good Hope (£15). The most notable item offered, however, is George Lily's map of Britain, 1546, of which the only other known, and slightly inferior, copy is in the British Museum, and was one of the six treasures selected from the British Museum for the International Geographical Congress in 1928. Apart from Ptolemy's atlas, this is the first printed map of Great Britain (£105).

Applications are invited for the following appointments, on or before the dates mentioned:—A secretary of the Iron and Steel Institute and editor of the *Proceedings*—The Chairman, Appointments Committee, Iron and Steel Institute, 28, Victoria Street, S.W.1 (Jan. 21). A full-time tutor for the practical course in social science at the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, 73, Strand, W.C.2 (Jan. 31). A professor of textile industries at the University of Leeds—The Registrar (Feb. 28). A principal of the School of Metalliferous Mining (Cornwall)—The Secretary to the Governors, Camborne (March 31).

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Disintegration of Light Elements by Fast Protons

SINCE the publication of our paper[1] on the disintegration of elements by fast protons, we have examined some of the light elements more carefully, using much thinner mica windows than we had previously employed on the high voltage tube. With the present arrangement, we can count particles which have passed through only 6 mm. air equivalent of absorber on their way from the target to the ionisation chamber.

In the case of lithium, we have found, in addition to the α-particle group of 8·4 cm. range, another group of particles of much shorter range. The number of these is about equal to that of the long range particles and their maximum range is about 2 cm. The ionisation produced by them indicates that they are α-particles. It will be of interest to examine whether any γ-rays are emitted corresponding to the difference of the energies of the α-particles in the two groups, but on account of the smallness of the effect to be expected, a sensitive method will be necessary.

In the case of boron, the number of particles observed increases rapidly as the total absorption between the target and the ionisation chamber is reduced. The maximum range of these particles is about 3 cm. and in our earlier experiments we determined the number of particles only after passing through the equivalent of 2·9 cm. of air, so that we were very nearly at the end of the range. Decreasing the absorber to 6 mm. of air gives an enormous increase in the number of particles. In this way about twenty-five times as many particles have been obtained from boron as from lithium under the same conditions. We estimate that there is roughly one particle emitted per two million incident protons at 500 kilovolts. The ionisation produced by the particles suggests that they are α-particles, and the energy of the main group would support the assumption that a proton enters the B^{11} nucleus and the resulting nucleus breaks up into three α-particles. There also seem to be present a small number of particles with ranges up to about 5 cm.

The Neutron and Neuton, the New Element of Atomic Number Zero

SINCE neutrons were first recognised by Chadwick in the rays from the beryllium nucleus, it may be of interest to note that in 1915 the hydrogen-helium theory[1] considered this nucleus to consist of two doubly charged helium nuclei and a condensed or nuclear hydrogen atom, now called a neutron. In a paper written early in 1919, the formula of the beryllium nucleus was given as $\alpha_2(\eta\beta)$ which in more recent symbols is $\alpha_2(pe)$, where the parentheses were used to emphasise the idea that the proton p and the electron e are united to form a neutral group or neutron.

The suggestion that neutrons exist as separate atoms was made independently at practically the same time by Lord Rutherford (June 3, 1920) and myself (April 12, 1920).

The basis for my assumption of the existence of neutrons, was that it would be difficult for α-particles, on account of their double positive charge, to pass through the region of repulsion (now called the potential barrier) around nuclei of high positive charge in order to unite with the nucleus, but that electrically neutral particles "could easily pass into and through this region". "Such atoms might have masses 1, 2, 3 and 4, and possibly other values, and they would contain no non-nuclear electrons, so they would have no chemical, and almost none of the ordinary physical properties, aside from mass."[2]

While the question of stability is not discussed in this paper, it may be stated that at that time I did not consider any neutron of higher mass than 2 to exist more than momentarily except in a moderately heavy nucleus, but that the first quadruple neutron present in other nuclei is that in argon 40, the nuclear formula of which may be written $\alpha_9{}^{++}(pe)_4{}^{\circ}$ or $\alpha_9{}^{++}(\alpha e_2)^{\circ}$.

Since neutrons of unit mass (according to Chadwick about 1·006), and possibly those of mass two also, probably exist throughout space, and are concentrated by gravitation in the planets, and still more in the stars, they may be considered to constitute collectively an element. Since the atomic number of an element is determined by the magnitude of the charge on the nucleus of an atom of the element, the atomic number which corresponds to a neutron is zero; that is, the neutron is a nucleus with a zero charge. As a name for this new element, neutronium, neutronon, or neuteron have been suggested to me, but the name 'neuton' is more simple and preserves in it the suggestion of neutrality and also the final 'on' of the chemically indifferent elements.

To what extent the atoms of neuton partake in the partition of heat energy between molecules in general, is an interesting problem, since the collisions of the neutrons would be with nuclei and with electrons, rather than with atoms and molecules.

It is not improbable that the general formula for any nucleus, $(p_2e)_z(pe)_i$, proposed independently in 1921 by Masson and by me, may be shown to have a theoretical significance. If n represents a neutron, then this formula may be written $(pn)_z n_i$ in which z is the atomic, and i the isotopic number. For the neutron z is 0 and i is 1, for the proton z is 1, and i is -1, for oxygen 16, z is 8 and i is 0, and for the principal isotope of argon z is 18 and i is 4. It is evident that if all of the electrons are present as neutrons, then $z+i$ gives the number of neutrons, z the number of extra protons, and $2z+i$ the total number of protons. The numbers z and i are the most important in the classification of atomic species, and the value of i defines specifically the particular isotope, either known or unknown, of any element, either radioactive or non-radioactive.

Kinetics of the Decomposition of Molecules of Intermediate Complexity

IN a large class of gaseous chemical reactions, the mechanism is generally supposed to be the following. Molecules are brought into an activated state by collision. Most of the activated molecules are deactivated again, but during their existence there is a definite probability of their chemical transformation. As is well known, the relation between reaction rate and pressure under these conditions is such that the reciprocal of τ, the half life of the reacting substance, gives a curve of type 1 or 2 (see Fig. 1) when plotted against the initial pressure[1]. (The precise shape of the curve before it has become horizontal depends upon how the above mentioned probability varies with the total energy of the molecule[2].)

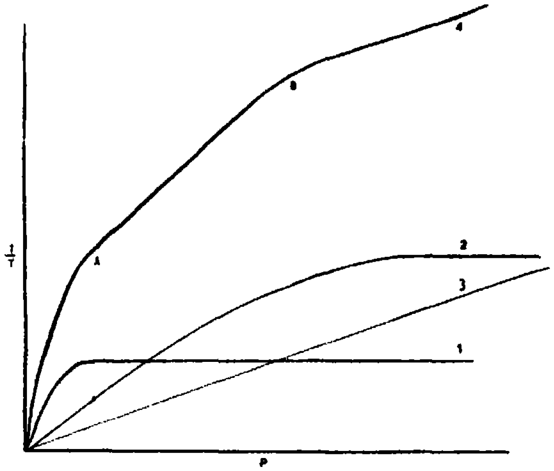

FIG. 1

In a molecule of moderate, but not too great, complexity, it seems possible that there may be several different modes of activation, corresponding to particular divisions of part of the energy among a limited number of vibrational (or rotational) states. To a first approximation, each of these modes may be associated with a separate probability of transformation, because, in the absence of collisions, internal redistribution may be difficult. Thus the total rate of reaction will be roughly the sum of several virtually independent reactions, each rate varying according to a curve of the type 1, 2, or 3. Since each of these reaches its limiting rate at a different pressure, the total rate may vary with pressure according to a segmented curve of type 4, with fairly pronounced changes of direction at A, B, and so on.

The simplest types of molecule may give curves which do not bend, at least up to high pressures, moderately simple molecules may give curves with a limited number of segments of decreasing slope, while complex molecules with many degrees of freedom give curves in which the segments merge into a single line without any noticeable changes of direction at particular stages.

The equation of the segmented curve in real examples will be very complicated, since the assumption of virtually independent reactions is to some extent an idealisation. Further, the variation of all the transformation probabilities with total energy may also complicate matters.

The object of this note, however, is simply (1) to suggest the desirability of exploring the hypothesis that the most general form of curve for molecules of 'intermediate complexity' is of the segmented type, and (2) to state that experiments on the decomposition of nitrous oxide at fairly low pressures (already published[3]) and further experiments on the decomposition of acetaldehyde (in progress) yield indications of the real existence of these different types of activated state.

'Hexuronic Acid' (Ascorbic Acid) as the Antiscorbutic Factor

IN view of the facts that (1) hexuronic acid is the name of a class of substances rather than that of one individual compound, and that (2) the material described as hexuronic acid isolated from adrenal cortex and now from Paprika contains a molecule of water less than is required for a hexuronic acid, we wish to ascribe the name ascorbic acid to the crystalline substance $C_6H_8O_6$ which has been the subject of earlier communications from our laboratories.

Methylnornarcotine, Glycuronic Acid, and Vitamin C

THE view that vitamin C is identical with methyl*nor*narcotine has been advanced by Rygh[1,2], who claims that narcotine occurs in unripe fruit and disappears with corresponding formation of vitamin C during ripening. According to Rygh, guinea-pigs receiving a scurvy-producing basal diet together with a suitable daily supplement of synthetic methyl*nor*narcotine lose weight and die but without any of the typical symptoms of scurvy. Other workers[3,4,5,6] have been unable to confirm this observation or to find narcotine in unripe fruit, and Dalmer and Moll[6] have shown that methyl*nor*narcotine as prepared by Rygh is not a single chemical substance.

In a later communication Rygh[7] has changed his ground and taken up the position that vitamin C is a complex, of which one component must be methyl*nor*narcotine while the other may be any uronic acid. Thus according to Rygh, the recently demonstrated anti-scorbutic activity of hexuronic acid is due to the contamination of the hexuronic acid by methyl*nor*narcotine, giving a mixture of the two components necessary for the make-up of vitamin C. This hypothesis was drawn from the observation that guinea-pigs were not only protected from scurvy but also grew normally if in addition to the basal diet they received daily 10 γ of "30 per cent methyl*nor*narcotine" and ½ mgm. of glycuronic acid, although the glycuronic acid alone neither prevented scurvy nor supported growth.

I have attempted without success to confirm these observations, using a specimen of glycuronolactone kindly given by Dr. E. L. Hirst, and two specimens of "30 per cent methyl*nor*narcotine", one prepared by Rygh and the other prepared in this laboratory. Young guinea-pigs were fed upon a scurvy-producing basal diet, and given a daily supplement of methyl*nor*narcotine, or of glycuronolactone, or of both together, in the amounts specified by Rygh.[7] On the sixteenth day the animals were losing weight rapidly, so they were killed and examined for (*a*) hæmorrhage at the knee-joint, (*b*) rib-beading, and (*c*) suprarenal staining with dilute silver nitrate solution after Moore and Ray.[8] All those animals which had been receiving any of the supplements showed signs of marked or severe scurvy indistinguishable from the condition of the negative controls, while the positive control animals (which had received 10 gm. of cabbage daily) were free from scurvy. The lower jaws of all the guinea-pigs were removed for histological examination of the teeth, and full details of the experimental observations will be published elsewhere when this examination has been completed.

Union of Pycniospores and Haploid Hyphæ in *Puccinia Helianthi* Schw.

THE discovery[1] that, in a heterothallic rust like *Puccinia graminis* Pers., or *P. helianthi* Schw., the transfer of pycniospore-containing nectar from a monosporidial (haploid) pustule of one sex to a similar pustule of the opposite sex induces the development of æcia in the pustule receiving the nectar has stimulated interest in the process by which the diploidisation is effected.

In the examination of free-hand sections of monosporidial pustules of *P. graminis* and *P. helianthi*, I have observed that usually two types of hyphæ protrude through the ostiole of a pycnium: (1) the stiff tapering slightly-curved paraphyses, which have been frequently figured; and (2) flexuous hyphæ which show considerable variation in length, diameter, regularity of outline, and a few other features. In some of the pycnia—probably the older ones—of a pustule, these flexuous hyphæ may show rather profuse development; in others, only a few of them, sometimes none, are discernible. They may be shorter, but usually they are as long or longer than the paraphyses, not infrequently two or three times as long. They may branch, but they rarely show septations. Some may be swollen at the tip. Occasionally a short spur or peg, of less diameter than a branch, juts out at a side or tip.

Several pycniospores in union with such hyphæ have been observed in sections of haploid pustules of *P. helianthi* in which the nectar had been previously intermixed, so that presumably both (+) and (−) pycniospores were present on the surface of each pustule and in close proximity to the protruding hyphæ.

Fig. 1 shows such a union. The pycniospore is empty; and the hypha has lost most of its cytoplasm. Presumably the nucleus of the pycniospore has passed through the connecting tube into the hypha and proceeded down it, to associate itself in conjugate relationship with some nucleus or the mycelium.

With regard to the short spurs or pegs on these hyphæ, it is assumed that a hypha of one sex, in response to the presence in its immediate vicinity of a pycniospore of the opposite sex, sends out a short tube to establish contact with that pycniospore.

A nucleus in the act of passing from a pycniospore into a hypha has not been seen, but empty pycniospores found connected by short tubes to these hyphæ furnish strong circumstantial evidence that nuclei migrate from pycniospores to these hyphæ by way of fusion tubes.

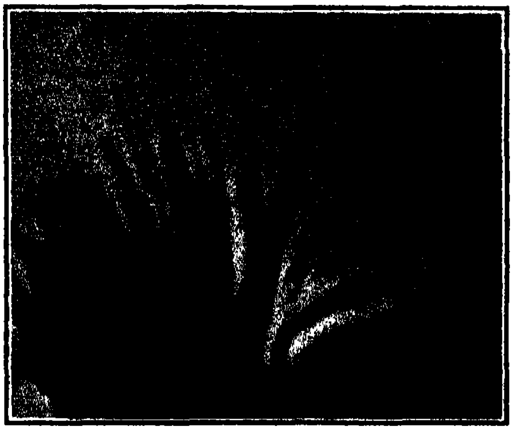

FIG. 1.—The union of a pycniospore and a flexuous hypha in a haploid pustule of *P. helianthi*. The pustule was fixed in formalin acetic alcohol 13½ hours after the intermixing of nectar was done. × approx. 1,500. Photograph by A. M. Brown.

Hyphæ which emerge through stomata and between epidermal cells were observed by Andrus[2] in haploid pustules of *Uromyces appendiculatus* and *U. vignæ*, and by Allen,[3] in haploid pustules of *Puccinia triticina*. Andrus regards these hyphæ as the tips of functioning trichogynes. Allen designates them "receptive hyphæ". However, neither of these investigators found direct evidence of fusions between 'spermatia' (pycniospores) and trichogynes or receptive hyphæ, although both assume from their studies that direct fusions do occur.

There is little doubt that, in haploid pustules of *P. helianthi* (or of *P. graminis*), the function of the protruding hyphæ is to establish contact between mycelia of one sex and pycniospores of the opposite sex and thus to serve as an avenue by which the nuclei of the pycniospores reach the internal mycelia of the pustules. The type of union so far observed simulates that of oidium and hypha in the Hymenomycetes.

Breeding of Oysters (*O. edulis*) at Port Erin

THE success obtained by the Department of the Ministry of Agriculture and Fisheries in breeding oysters (*O. edulis*) in the experimental tanks at Conway and Lympne[1] suggested that a similar use might be made of the large outdoor tanks or ponds at the Port Erin Marine Biological Station. In normal summers the sea temperature in Port Erin Bay rarely rises above 59° F. seawards of the beaches, owing to the steepness of the beaches and the mid-sea position of the Isle of Man; the maximum is reached at about the end of August[2]. The stagnant water in the ponds, however, follows air temperature much more closely than the sea, and this year gave surface readings during July and the first three weeks of August ranging mostly between 62° and 65° F.; a range favourable for oyster breeding.

In February, a hundred Whitstable oysters were imported into the Port Erin tank system and distributed on April 14 experimentally on the bottom in different outdoor tanks. These oysters were examined on July 20. High mortality had occurred in the east tank where about a hundred plaice had been stored for breeding. On the bottom of this tank it was found that there had become deposited a black sludge bearing a luxuriant growth of green weed. Oysters which occurred in places where this sludge had accumulated were suffocated. Somewhat similar conditions obtained in parts of the west tank, though the sludge was less dense and the loss was not so heavy as in the east tank. Only one individual, however, among twenty-five had died in a small clean outside store tank through which a small circulation of water had been maintained.

The oysters from this latter tank (24 in number) were opened on July 20, when two individuals were found black sick, that is, carrying larvæ ready to be voided from the parent into the water. On July 13 the east tank had been refilled with water direct from the sea after the pond had been scrubbed out. In this pond most of the larvæ taken from the two black sick oysters were distributed on July 20. To this tank had also been added about a hundred plaice stored for breeding experiments in the following year.

On November 24 the tank was emptied and examined for oyster spat. A sprinkling only was found. Sixteen were found attached to the north wall of the tank in underhung places along with balanids, mostly remote from direct sunlight. Three occurred in the full glare of daylight on the bottom and near the middle of the tank; one settled on a varnished board and one on a stone, both in deep water near the outlet pipe; two occurred on mussel valves also on the bottom of the tank. The bottom and lower parts of the walls of the tank were covered with a growth of long delicate green weeds, 98 per cent of which were *Cladophora fracta*, Kütz, var. *flavescens* Batt. (*C. flavescens* Harv.), along with a little *Urospora isogona* Batt. and *Percursaria percursa* Rosenv.; there was very little accumulation of black mud. It is probable that a good fall of spat might have been obtained had settlers or a supply of cultch been placed in the pond. The spat varied in size from 6 mm. long by 6 mm. deep to 20 mm. long by 18 mm. deep, and fell into two size groups, suggesting that two periods of settling occurred, possibly a settlement from each brood of larvæ.

Ordinary sea-water of a salinity about 33·5 per thousand[2] pumped into the tank direct from the sea was used in this experiment; the salinity probably varied little during the first month of the experiment, as this was a period of drought and a little fresh sea-water was pumped into the tank from the sea daily. The plaice in the tank were fed on boiled mussels, the remains of which would contribute with the waste products from the plaice themselves towards manuring the water for the growth of those micro-organisms on which the oyster larvæ and spat thrived. A heavy growth of green weed is evidence of considerable production of motile reproductive bodies from these plants. These reproductive bodies may very well have formed a portion of the food of the larvæ and/or spat at some period. Scott's investigations[3] on the plankton of these ponds in 1924–26 indicate that in July and August the phytoplankton (diatoms and dinoflagellates only) may normally be relatively scarce, or even absent: no plankton observations were made in 1932. A few *Gobius ruthensparri* and about four specimens of various species of small flatfish in the pond may have been inimical to a larger spatfall by feeding on the larvæ, as Dodgson and Sherwood[1] have found. 106 living plaice were recovered from the experimental tank in good condition on November 25.

The experiment is interesting in proving that under such meteorological and other conditions as prevailed in the summer of 1932, (*a*) oysters will spawn in the tanks at Port Erin; (*b*) the tanks are suitable for the production of young oysters; and (*c*) when the method of cultivating oysters in tanks has been improved so as to become a sound economic proposition, it may be possible in favourable summers to produce oyster spat in great numbers at Port Erin. The experiment also encourages the reasonable hope that such tanks as may be built in the future for mussel purification in the north of England may become as useful as those at Conway for oyster breeding.

We are indebted to members of the staff for taking valuable routine temperature records.

Reversible Stoppage of the Blood Circulation in Sabellids

SABELLIDS are marine polychæte worms, the blood system of which is peculiar, both anatomically and physiologically. Numerous capillaries are present, in the body wall, in the branchial crown, and projecting freely into the body cavity, all of them ending blindly. Most of the blood vessels in the body contract rhythmically. By peristalsis blood is forced along the continuous vessels, and at intervals of 10–20 seconds blood is expelled from the blind capillaries by regularly rhythmic centripetal contractions of their walls, to flow back again into these capillaries almost immediately. There may thus be said to be a true Galenic circulation in the capillaries. The blood contains the respiratory pigment chlorocruorin.

If a sabellid worm is put, under water, into a narrow glass tube, the rhythmic contractions of the blood vessels in its crown can be seen through the glass. Under these conditions the contractions continue for half an hour and then cease. But as soon as even the tip of the crown projects again beyond the end of the tube, the contractions recommence. Thus when worms in Nature have retired into their tubes for over half an hour their blood no longer circulates. Yet *Spirographis* can remain uninjured for eight hours inside its tube when the front end of the latter is artificially closed. After about eight hours the animal re-expands its crown through a new anterior lateral aperture which it forms by local digestion of the mucoid tube.

When a sabellid is put into sea water saturated with carbon dioxide, the pulsations of its blood vessels cease almost immediately. After the animal has been put back into pure sea water the pulsations recommence. Neither water lacking dissolved oxygen, nor water acidified with hydrochloric acid to the same pH as water saturated with carbon dioxide, stops the pulsations. The threshold pH for stoppage in water containing carbon dioxide is in the region of 6·0, varying slightly with species.

It has been concluded from a variety of experimental evidence that the natural inhibition of blood circulation when worms are in their tubes is due to an accumulation of excreted carbonic acid between the filaments of the closed crown, and that this carbonic acid does not act on the blood vessels through a nervous reflex, but it prevents the normal exit of carbonic acid produced in metabolism, which accumulates in the body and has a direct inhibitory action on the blood vessel walls.

A full account of this work will be published shortly.

Photochemical Reaction of Hydrogen and Chlorine

I AM much surprised to read, in NATURE of December 17, that so fine an experimenter as Prof. A. J. Allmand has failed to inhibit the action of light on a mixture of hydrogen and chlorine, by drying. It is, with one exception, the easiest reaction with which to demonstrate the influence of traces of water on chemical action. So much so, that for many years it was one of my stock experiments in courses of elementary lectures.

Hydrogen and chlorine were generated by the electrolysis of hydrochloric acid, washed with water and conducted through a tube of phosphorus pentoxide for rough drying. The mixture then passed through a dozen thin bulbs blown in series on a tube of soft glass, in some of which had been placed phosphorus pentoxide. After about six hours, the wash water was saturated with chlorine, and half an hour later the bulbs were sealed off at their capillary joinings. The last bulb was exposed to the light of burning magnesium, and if it exploded after five seconds, the batch was assumed to be perfect. In lecture a pair of bulbs, one containing phosphorus pentoxide and the other not, were exposed to the same intensity of light and in no case did the dry gas ever explode, while the moist ones did so without exception. One of the dried bulbs was exposed to bright sunlight for three days, and analysis of the gas afterwards showed that one third of the mixture was still in the uncombined state. Mellor and Russell[1], in repeating this experiment, found that two thirds of the gas had resisted the action of light.

In describing these experiments to the Chemical Society, I did the experiment successfully; in fact, on the principle that 'seeing is believing' I have, almost without exception, demonstrated my results experimentally at the meetings at which the papers were read. Prof. Bodenstein and Prof. Allmand owe, I think, the failure of their experiments to the complexity of their apparatus. It is almost impossible, on account of the slowness of diffusion, to dry an apparatus which has any dead ends. Mere 'baking out' at 200° is insufficient, as I have shown over and over again, to get rid of deep-seated moisture in glass. Long continued contact of a gas with pure phosphorus pentoxide is the only way in which success can be attained.

At the risk of seeming egotistical, I would ask all who contemplate working in this field to read my paper[2] on "Manipulation in Intensive Drying". If they do so, they would, I feel sure, save themselves much fruitless effort.

Limiting Mobilities of some Monovalent Ions and the Dissociation Constant of Acetic Acid at 25°

MACINNES, Shedlovsky, and Longsworth in reply[1] to our recent letter with the above heading[2] have asserted, without experimental evidence, that our conductivity technique was subject to errors and that the discrepancies between the results are to be attributed to this cause. We would, however, point out that by using the cell constant determined with 0·01 N potassium chloride by Parker and Parker's method[3] we have been able to reproduce Kohlrausch and Maltby's results[4] for KCl, NaCl, and KIO_3 at 18° over the range 0·0001 – 0·01 N to within 0·1 per cent,[5] and this, it appears to us, gives definite support to the view that our experimental results are trustworthy to at least 0·1 per cent.

Two limiting cation transport numbers for KCl are given in our paper[5], namely, 0·497 the old classical figure of Kohlrausch and Maltby[4], on which basis all limiting mobilities have hitherto been calculated, and 0·490 the most probable figure deduced from the results of MacInnes and Dole[6]. It was our original intention to redetermine this constant but owing to the transfer of the senior author to Woolwich, this project was abandoned. We now employ the figure 0·490, which appears to be the most probable value deduced from the determinations of MacInnes and Dole and of Longsworth[7]. The American authors state in their letter that their value for the limiting conductivity of the chloride ion, based on conductivity and also transport number measurements of KCl, NaCl, LiCl, and HCl at 25°, is 76·32 "within a few hundredths of a per cent"; the value deduced previously by us was $76{\cdot}4_5$ (n_k for KCl = 0·490).

The use of the empirical formula of Shedlovsky[8] for extrapolation to infinite dilution seems unnecessary: the ordinary square root formula holds over a considerable concentration range when applied to Shedlovsky's results[3] for KCl, NaCl, and HCl at 25°. Further, the Shedlovsky equation is of limited applicability (it breaks down for KNO_3, chlorates and iodates) and the values for Λ_0 deduced from it for NaCl and KCl at 18° have actually been exceeded at experimental concentrations by Kohlrausch and Maltby[10] and by Wieland[11] respectively.

'Raw' Weather

With the return of winter the following physico-physiological question once more calls for solution:—Very hot but dry weather may be tolerable, while moderately hot but very damp weather may be almost unbearable. The explanation of this in terms of cooling by evaporation is known to everyone. Again, while very cold dry conditions may be pleasant and invigorating, damp and rather cold weather—what is generally described as raw weather—is very unpleasant even to normal people, while it is peculiarly bad for those suffering from rheumatism and the like. So far as I know no explanation of this last effect has been generally accepted; indeed, inquiries of many physicists and not a few physiologists have failed to produce any suggestions regarding even the general lines along which a solution might be found. Any complete explanation must also account for the fact that damp air with a moderate temperature is far from unpleasant, as exemplified by the mild south-westerly conditions often occurring in the British Isles.

G. M. B. Dobson.

Robinwood, Boar's Hill,
Oxford.

Heat expands and softens the tissues, bringing more blood and lymph into the parts: cold tightens them up. It is, I suggest, this change which leads to pain in rheumatic people. A sudden thaw is most trying.

Cold moist air has a much higher conductivity than cold dry air, and acting on the skin produces the raw feeling and excites the nerve endings which reflexly cause the tightening-up effect.

The action of certain infra-red rays in producing reflexly congestion of the nasal air way or the opposite affords a striking example of how skin stimulation produces reflex effects on deeper organs.

Isotope Effect in the Spectrum of Cadmium Hydride

In an earlier paper[1], I dealt with the structure of different band systems in the spectrum of cadmium hydride. In several respects, however, my analysis suffered from incomplete resolution of the spectrum, especially regarding the isotope splitting of the band lines. Recently I repeated the investigation, using a large concave grating in the third order (0·6 A./mm.). Much work was devoted to the analysis of an extensive system $^2\Sigma^* \rightarrow {}^2\Sigma$, covering a wide range of vibrational levels ($v' = 0$ to 13, $v'' = 0$ to 6) and thus forming a favourable case for an examination of the isotope effect. The band lines are here split into components belonging to Cd (114, 112, 110, 116), already known from the work of Aston.[2] Besides this, faint components appear belonging to isotopes Cd (118, 108), which have not been reported before. These components were found in every rotational line-group of a great number of bands, falling exactly in the position calculated ($\pm$ 0·02 cm.$^{-1}$). I was not able to detect the components of the odd isotopes Cd (111, 113), due to their positions between the intense lines of Cd (110, 112, 114). Only in favourable cases could a diffuse blackening be distinguished between the components of Cd (110, 112), which may be related to Cd (111).

There are some peculiarities regarding the intensity distribution among the isotope components which may be of interest to mention. In bands belonging to the transitions $v' \rightarrow 0$, the lines of Cd (114) are somewhat more intense than those of Cd (112), while there is a considerable intensity difference between the lines of Cd (110) and Cd (116), in agreement with Aston's values. In transitions $0 \rightarrow v''$, the intensity distribution is changed in favour of the heavier isotopes. Due to this, I was able to trace Cd (118) only in the latter case, where it appeared stronger than Cd (108), while in transitions $v' \rightarrow 0$ only Cd (108) could be observed. These relations can be accounted for partly[3] by influences of the Boltzmann factor $e^{-h\nu/kT}$.

Detailed account of the analysis of this spectrum will be given shortly.

Chlorination of Sodium Benzoate

The chlorination of benzoic acid in alkaline solution by means of sodium hypochlorite is often quoted as an example of the effect of ionisation on orientation. Lossen's experiments[1] have been repeated, and it is now found that the product of chlorination contains 48 per cent ortho-, 32 per cent meta- and 20 per cent para-chlorobenzoic acid. This is an unusual type of orientation.

Research Items

Burial of a Bari Rain-maker. The burial of a rain-chief in the Bari country, Mongalla Province, Sudan, is described by Mr. A. C. Barton in *Sudan Notes and Records*, vol. 15, pt. 1. The rain-maker's last illness took place during a drought, and, as was ascertained by the performance of a special rite, had been caused by a more powerful rain-maker, who attributed to him the failure of his own efforts to bring rain. The grave was of a special type reserved for rain-makers, chiefs and influential freemen. It lay from east to west, and from the west, descent to the bottom of the excavation was by two steps cut in the earth. The interment chamber proper was cut laterally and frontally into the north and east sides of the excavation. The funeral ceremonies began with secret rites, to which only the close kin were admitted, in the house, which was closed immediately after death. These rites included the shaving and anointing of the corpse, the hair being placed in a calabash to be disposed of later in the bush. At the graveside, women who had not been present inside the house again anointed the body over its clothes, and the sons after anointing the back of the corpse down to the waist, again over its clothes, with ground and burnt semen returned to the house, observing a grass taboo, in walking, where they remained until earth had been thrown into the grave. A small son of a serf had been chosen as a serf of the dead, and when the corpse had been laid to rest in the chamber as on a bed, this boy remained by the corpse until it opened in final decay, when he came out of the grave and proclaimed the chief really dead. Large slabs of stone, sacking, etc., blocked the entrance of the cavity, so that no earth could fall on the chief, and above the grave were placed carved grave stakes, of which one had two prongs, a 'male' and a 'female', while the smaller is the 'sentinel'. These were brought from the father's grave and will remain on the chief's grave until required for his son's burial. A mourning feast and dance follow the burial.

The Malabar House. In commenting on a ballad of Kerala in the *Indian Antiquary* for November, Dr. M. D. Raghavan appends some notes on the Malabar house, which is highly conventionalised in plan and clearly has retained its main features unchanged for a very long period of time. The most characteristic dwelling-house of Kerala is called *nâlu-pura*, literally 'four-houses', being built round the four sides of a courtyard which is open to the sky, each room being named relatively to its situation with regard to the courtyard, that is, southern room, northern room or the three western rooms. Every house, however small, is regarded conventionally as a *nâlu-pura*, and hence a house of the smaller type, though facing east, is called *paḍiññâṟṟa pura*, that being the western block consisting of three rooms with a verandah in front. Usually behind the central room of the western block there is a small room called the 'lean-to'; and beside the inner verandah is an outer verandah with a long ridged roof on a beam supported by high pillars. The central of the three western rooms is the principal room of the house, containing the valuables and sacred to all household ceremonies. The main entrance is through a portico which serves the purpose of a drawing-room. Each house stands in a compound of its own, which is thickly planted with trees, and is enclosed by a massive bank of earth. A broad smooth walk, well rammed and plastered with cowdung, leads to the courtyard, of which the surface has been treated in the same way. The courtyard is used for drying paddy, pepper, etc., in the sun. It serves as a threshing floor, as the recreation-ground of younger members of the family, as an exercise ground in the use of arms, and as a place for ceremonial and social functions.

Facial Growth in Children. "Facial Growth in Children", by Corisande Smyth and Matthew Young (Medical Research Council. Special Report Series, No. 171), gives the results of a study of twenty characters of the face in 1,400 London children. The primary object of the investigation was to establish standards of normality. Measurements were made of some 1,200 selected children aged 8–14 years in the London County Council schools, 100 boys aged 9–10 years taken at random from a group of boys of the same age, and 100 children aged 2–5 years attending a welfare clinic. No measurements were made of children aged 5–8 years. This study confirms the findings of John Hunter, Tomes and Bolk that the dental arch does not increase in length after complete eruption of the milk teeth, but Smyth and Young find there is a definite increase in breadth of the dental arches after four years of age. As regards inter-relationships of the facial measurements, the most interesting result is the high association between the zygomatic breadth and breadth of the dental arches, an association denied by Korkhaus and other observers. There appears to be some tendency for a narrow face to be associated with a high palate but not necessarily with a narrow dental arch. Although all the results are based on selected children, that is, on those in whom normal occlusion has occurred, Smyth and Young consider they may be taken as fairly representative of London school children because of the close agreement found in the results for two groups of boys aged 9–10 years, one group selected because of normal occlusion, the other taken at random from the London schools.

Influence of Living-Space upon Growth. In the course of two years, experiments, fifteen in number, have been carried out by Dr. Jan Podhradsky with the object of deciding whether the size and shape of the living-space influenced in any way the growth and development of tadpoles of *Rana fusca* (*Bull. de l'Instit. Nat. Agron. Brno*, CSR., Sign. C. 20, 1931). It was found that size of living-space had a bearing on growth and development so that they followed their normal course only within certain limits of space, above and below which growth was depressed. In a small living-space the adverse factor appeared to be mutual disturbance amongst the tadpoles; in a large living-space the isolation of individuals seemed to be largely responsible. Shape of living-space also had a measurable influence: narrow and high vessels depressed growth because they enforced and exaggerated vertical movements on the part of the tadpoles and caused greater reciprocal disturbance, as well as allowing only a low absorption of oxygen at the surface. These effects were intensified with the growth of the tadpoles. It was found also that abnormally low water depressed growth and development, and this relation was thought to be due to the unusual accumulation of excretory products and the fouling of food.

Age and Growth of Limpets. N. Abe (*Science Reports*, Tôhuku Imp. Univ., vol. 7, No. 3, 1932) has shown that colonies of *Acmæa dorsuosa* formed in spring and summer break up in autumn and winter but the individuals do not migrate more than 5–6 metres and hence are subject to the same environmental conditions every year. He has measured the individuals of such colonies and also other examples in which the shell clearly shows the annual rings. In limpets which live in wet places the growth-rate is greater, the thickening of the shell is slower and the height of the shell is relatively less than in those from a drier locality. The ratio of breadth to length of the shell is practically constant in individuals more than three years old. The weight of the shell is greater than that of the body (soft parts) in the proportion of 1 : 0·8. The frequency distribution of age in the colonies is asymmetrical; individuals of four years of age are most numerous. Specimens older than twelve years are few and it would appear that the maximum age of this limpet is about seventeen years.

Style-Sac of Gastropods. R. V. Seshaiya (*Rec. Indian Mus.*, vol. 34, pt. 2, 1932) notes that a crystalline style and style-sac have been recorded in ten families of prosobranch gastropods, and he now records them in two more families—Cerithiidæ and Assimineidæ. He refers to Randles' description (1902) of the posterior chamber of the stomach of *Turritella* in which the presence of a single fleshy fold and a crescentic groove is recorded, the groove being considered to be a vestigial cæcum and a very primitive feature. The author's examination of the stomachs of *Turritella* and of several other style-bearing gastropods does not support this view. The groove and the adjoining ridges or folds are functional structures and serve to accommodate the gastric shield and to direct the gastric contents towards the style.

Nutritive Value of Pastures. The fact that pastures which appear very similar may differ widely in nutritive value (stock-carrying and fattening capacity) has long remained without a satisfactory explanation, and an investigation of the problem has been made by E. J. Sheehy (*Sci. Proc. Roy. Dub. Soc.*, vol. 20). So far as the chemical composition of the dry matter of the organic portion of the herbage is concerned, no consistent difference was observed between good, mediocre and poor pastures in the same neighbourhood, and although a slight inferiority in the phosphate content of the inorganic portion did occur in the poorer herbage, the disparity was not large enough to account for its reduced feeding value. Further, the chemical composition of the dry matter of fiorin grass and plantain grown on soils carrying pastures of very different value, remained unaffected. The digestibility of such different types of pasture plants as perennial rye grass, Yorkshire fog and plantain were also found to be very much alike, so that differences in nutritive value could not be explained on this score either. The factor which proved to indicate the value of the pasture, however, was the percentage of dry matter, and in consequence the density of the sward is an important feature. The latter is largely determined by the botanical personnel, the narrow-leaved grasses yielding a higher dry weight per unit area than broad leaved plants such as weeds. Clovers occupy an intermediate position. Fattening capacity is, therefore, definitely related to the dry matter content and density of the herbage, but stock-carrying capacity is also affected by the rate of growth, as upon this property the provision of abundant feed depends.

Identification of Indian Sleeper Woods. In *Forest Bulletin* No. 77 (Economy Series, of the Forest Research Institute, Dehra Dun, 1932) Mr. K. A. Chowdhury, wood technologist, has produced a most useful little guide to enable forest officers, railway passing officers and others to identify on the spot some of the more common Indian sleeper woods. This bulletin is the first of its kind. Capt. Trotter in a preface says that it is hoped to publish similar bulletins from time to time dealing with timbers of individual provinces, that is to deal with timbers according to localities rather than uses. In the present case that method of treatment would not have been so useful, as the map appended to the bulletin well illustrates. This map "shows the various species of sleeper woods that grow in the areas in which different railway groups are concerned". These groups are five in number, namely, Northern, Central and Terai, Eastern, Southern and Burma. The map serves two purposes—the first and most obvious, the species which can be obtained from a given locality, and the second and the more striking, it can help in identification, as a species may easily be eliminated which does not occur in a particular locality. A few simple details on wood structure and so forth lead up to the key for the identification of more than fifty species of important Indian sleeper woods. This key is drawn up in the simplest fashion and appears to be easily workable, but as the author states, "quick and accurate identification of timbers can only be achieved after much practice". A sharp knife and a hand lens magnifying 10–12 times are all that are required to assist the key. Incidentally, the bulletin serves once again to show the importance to India as a whole of the research work being carried out at Dehra Dun in connexion with the enormously valuable Indian forest estate.

Spectroscopic Detection of Small Quantities of Elements. The *Wiener Berichte* IIb 141 contains a paper by W. Späth on the detection of very small quantities of elements by the spectroscope. Droplets of solutions were evaporated on silver or copper electrodes and the spectra were excited by condensed spark or by a break-contact arc, according to whether spark or arc lines are the more persistent in a particular case. The preparation of very pure silver electrodes was a long and troublesome matter, and the methods finally adopted are described in considerable detail. 10^{-10} gm. of cadmium was the smallest quantity which could be detected, using the arc line 2288 A. and the spark line 2265 A. In experiments with other metals, 10^{-10} gm. manganese, 10^{-7} gm. arsenic, 10^{-7} gm. tellurium, 10^{-9} gm. lithium and 10^{-11} gm. strontium could be detected. The limit is apparently set by the presence of a continuous background in the spectra which masks very faint lines, and it is suggested that a spectrograph with higher dispersion combined with high light gathering power would enable yet smaller masses to be detected.

Low Temperature Carbonisation of Coal. In accordance with the policy adopted by the Government some years ago, the Department of Scientific and Industrial Research has examined the Turner plant for the low temperature carbonisation of coal installed at the Comac Oil Co. Ltd., Coalburn, Lanarkshire. The report on the test issued by the Department (H.M. Stationery Office, 9*d*. net) shows that the retort is of the continuous vertical type, internally heated by superheated steam. A peculiarity is the use of a fluctuating pressure claimed to facilitate transfer of heat from the steam to the coke. From 1 ton of coal were obtained 13·4 cwt. of coke, found to be a good domestic fuel, 21·3 gallons of tar and spirit, 2,170 cub. ft. of gas of total heating value 18·7 therms, and 334 gallons of liquor of no value, although as an effluent it must be regarded as a distinct liability. The alternations of pressure are regarded as a necessary feature of this process, but tests made with the plant adjusted to give steady and fluctuating steam pressures to the retort gave substantially the same results.

Dewaxing and Acid Refining Mineral Oils. At a Congress of Polish Petroleum Technologists two years ago, the De Laval *S–N* method of dewaxing was for the first time made public. The data then were based principally on tests with Polish oils from Schodnica and Urycz. Tests were being carried out on a small plant, but since that time a larger centrifugal separator has been employed successfully, and it has been possible to treat pipe-still distillates in addition to those produced by other methods. An account of this process was given by Dr. Nils Olof Backlund on December 13 at the Institution of Petroleum Technologists. Among interesting points made was the substitution of trichlorethylene as a more suitable solvent for separating the wax from the oil than the time-honoured benzene. Rate and degree of cooling of the oil-solvent mixture are of the utmost importance to the process. The advantages of the De Laval *S–N* trichlorethylene method compared with the benzene method include a smaller quantity of solvent used, a shorter period of cooling and the possibility of working at higher temperatures. Particulars were also given regarding acid treatment of petroleum products, and it was concluded that this process had not reached an entirely satisfactory stage. Fundamentally, acid treatment still remains a 'discontinuous process', and suffers from the disadvantages thereof when compared with efficiency of distillation, dewaxing and cracking in continuous plants. The author pointed out directions in which modernisation of acid-refining is desirable and gave an account of the De Laval *S–N* acid sludge separator, which represents a definite advance on anything so far designed. The main importance of this process, however, would seem to be in the field of lubricating oil refining, where it is destined to effect considerable economy in production costs.

Astronomical Topics

Astronomical Notes for January. Mercury can be observed as a morning star early in the month; Venus is also a morning star, but far from the earth, and approaching superior conjunction; its disc is almost fully illuminated. Mars is approaching opposition, and is visible for most of the night; this is an aphelion opposition; the diameter on March 3 will be just under 14″. Jupiter also reaches opposition in March, and will be near Mars for some months. Saturn is in conjunction with the sun in January; Uranus is still observable in the evening. Neptune is well placed for observation in the middle of Leo.

A star of mag. 5·6 is occulted by the moon on Jan. 9, disappearing at 8.28 P.M. κ Geminorum (mag. 3·6) disappears at 10.50 P.M. on Jan. 11, reappearing at 11.24, angle 221°; the moon is full on that day.

The following are the positions of Comet Dodwell-Forbes at the beginning of Jan. 14 and 24, according to the Whipple-Cunningham orbit:

Jan. 14 R.A. $0^h38^m34^s$ S.Decl. 4° 52′; Jan. 24 R.A. $1^h15^m4^s$ N.Decl. 4° 43′.

Comets Faye and Geddes may also be seen with moderate telescopes; there are ephemerides in the B.A.A. Handbook for 1933.

There are minima of Algol at convenient times for observation on Jan. 8 at 7.54 P.M. and on Jan. 28 at 9.42 P.M.; a full table is given in B.A.A. Handbook.

Mass of Eros. Soon after the announcement by W. H. van den Bos and W. S. Finsen that Eros appeared like a figure-of-eight in the 26½ in. Johannesburg refractor in January 1931, Prof. W. H. Pickering derived the mass of Eros on certain assumptions as to its figure. Dr. Knut Lundmark has made a further investigation based on the same material (*Lund. Obs. Circ.*, No. 7). The diameter of Eros was taken as 23·4 km., and it was supposed to consist of two spheres in contact, each having a radius of 5·85 km.; the reciprocal of the mass in terms of the earth is 259,900,000. This gives a density only a quarter of that of the earth. If the distance of centres is increased to 18·6 km., the density becomes equal to that of the earth.

Comets of A.D. 868 and 1366. It was established by Dr. Hind that the second of these comets is in all probability identical with Tempel's Comet, 1866 I, associated with the Leonid meteors; Hind thought that the comet of 868 might also be identical with it. The *Japanese Astronomical Herald* for October, 1932, contains a re-investigation of the orbits of these two comets, by Dr. S. Kanda, based on the original observations; for the first comet he used observations made in Japan, Europe, and Korea; for the second he does not appear to have found any further observations than those used by Dr. Hind, and the new orbit is quite close to that of Hind.

T	868 March 4	1366 Oct. 18·54 U.T.
ω	277°	164·8°
Ω	305	218·5
i	65	149·8
q	0·42	0·9749
e	1·00	0·9059
Period	—	33·35 years (assumed)
Equinox	868·0	1366·0

It may be concluded that the first comet is not identical with Tempel, but that the second probably is identical. This identity had been assumed by the Computing Section of the British Astronomical Association in investigating the perturbations of the comet from 1366 until 1932. Search ephemerides are given in the B.A.A. Handbooks for 1932 and 1933.

Electricity, Gas and Other Fuels as Heating Agents

IN a paper read by Mr. A. H. Barker to the Institution of Electrical Engineers on December 1, an explanation was given of the conditions under which electrical power can be used competitively for the heating of buildings. It is well known that, reckoned on the heat unit basis alone, electricity is the most expensive of all the sources of heat in common use, and that comparatively, gas is at present not very far behind it. Since the heat in a gas company's therm equals 29·4 electric units, it follows that if gas cost 6*d*. per therm and electricity 0·5*d*. per unit, the cost of the crude heat per therm delivered by the gas company would be 6*d*. and by the electric company 14·7*d*. In a few years' time we hope that more companies will be supplying at these cheap rates. If the thermal electric storage were employed the price of the electric heat would be reduced by about forty per cent. With oil at 80*s*. a ton and coke at 40*s*. a ton, the costs would be 2·25*d*. and 1·64*d*. a therm respectively. Looking merely at the costs of the 'crude' heat, the solid fuels are much cheaper.

The most fundamental difference between gas and electric heat is that with the former it is purified fuel which is transported to the spot where the heat is required, while with the latter it is energy only. There are three points arising from this. The street main is much larger and more difficult to accommodate with gas than with electricity but the house-pipes for gas are smaller and cheaper. In order to convert the gas energy into heat, it has to undergo the process of combustion with the disadvantages of high temperature and waste products of combustion. The use of gas causes less actual destruction of fuel than electricity and the heat from it is therefore cheaper. Gas is in fact crude fuel which has had all the ashes and smoke purified out of it at the sacrifice of the manufacturing costs and about twenty per cent of the energy of the crude fuel. Electricity carries the purification a stage further. In its manufacture, everything, including all the labour, is purified out of the fuel but there is a loss of about twenty per cent of the energy in the mains. There are obviously cases, where so far as its usefulness is concerned, this further stage of purification is a pure waste of money, just as it is a waste of money to soften water needed for sanitary fittings.

In Mr. Barker's opinion, gas and electric supply have each their own sphere of usefulness, in which one is either economically or functionally superior to the other. There is only a small area of supply in which reasonable competition is legitimate. Both industries ought to be amalgamated, in their own and in the public interest. It is very difficult to assess the money value of their relative advantages and disadvantages in each particular case.

Apart from its cost, electrical energy is almost an ideal means for room warming. By its agency, pure heat can be delivered through light and flexible wires in any quantity, at any temperature and in any desired form to any particular spot. Turning on and off involves nothing but a mechanical motion of a switch and this can be readily done automatically by a simple and trustworthy form of thermostat. The use of any other fuel gives, along with the heat, products of combustion of a more or less deleterious nature. It is only in very special cases that heat derived from the combustion of fuels can be employed without the use of chimneys.

Gas possesses the advantage that it can be exactly regulated to requirements. It can be conveniently stored so that a sudden overload need not affect the supply. Breakdown is less probable than with the more complicated electrical plant. In some cases when combustion is effected completely, the products are innocuous and so can be allowed to mix with the air of the building and so secure—like the electrical fire—an efficiency of one hundred per cent. The drawbacks are that gas needs to be ignited and supplied with air before the heat can be developed. It has an objectionable smell and is dangerous if it escapes or is incompletely burnt.

The advantages of oil are that it is fluid and so can be pumped with little smell or trouble into a tank through a pipe-line. It is much easier to ignite, to regulate and to extinguish than coke, though more difficult than gas. It is very clean in operation, and when properly burnt highly efficient. Owing to the high degree of the combustibility of oil, there is a good deal of potential danger attached to it. It is apt also to give off smoke and odorous fumes. The advantages and disadvantages of coke and other solid fuels are well known. For example, they will allow any sort of combustible material to be destroyed in the furnace. It is probably the most economical form of heating but it involves greater labour than any other fuel. It produces dust, is dirty to deliver and clumsy to handle.

Mr. Barker deals exclusively with the cost of the fuel and the labour involved in handling it. When the heating required is intermittent, both electrical and gas heating have advantages over the other fuels.

Mesolithic Age in Britain*

IN 1926 the Royal Anthropological Institute held an exhibition illustrating the microlithic industries of Britain, to which all who were then known to be interested and engaged in forming collections of implements of this phase of the Stone Age were asked to contribute. The mesolithic period had been somewhat neglected by British archæologists; and it is probable that it came as a surprise, even in archæological circles, to find how considerable was the amount of material which it had been possible to get together and the increase in the interest taken during the early years following the War in these remarkable products of man's skill and ingenuity.

In the period which has elapsed since that exhibition was held, further progress has been made in the study of the mesolithic age, and the time was fully ripe for a detailed discussion of the position of microlithic industries in relation to preceding and succeeding cultures. The opportunity for such discussion was afforded by a series of papers in the programme of Section H (Anthropology) when the

---

*Based on certain papers read before Section H (Anthropology) of the British Association at York, September 6, 1932.

British Association met at York last summer. The conditions were exceptionally propitious, as not only were there within reach of York sites of sandy heath typical of the geographical environment preferred by Tardenoisian man, upon which, moreover, numerous finds of implements had been made, but also the fact that Mr. J. G. D. Clark was to open the session with a paper on the mesolithic age in Britain ensured that the otherwise preponderating attention to be given to the north of England in this series of communications would be placed in proper perspective.

The advances which have been made in the study of the typology of mesolithic implements now make it possible to work out the geographical distribution of characteristic forms with a relative certainty, if not with an absolute precision, while a number of pregnant suggestions emerges as to their derivation and development. Thus Mr. Clark holds that, while the Upper Palæolithic industries of Britain already showed microlithic tendencies, the Tardenois culture is to be regarded as intrusive in both its first and second phases, and late Tardenois, though in all probability a local development in its British manifestation—the 'trapezoid' implement is said to be peculiar to Britain—also has indications of continental influence. Thus in the Pennines the 'broad blade' industry, the non-geometric Early Tardenois industry, is certainly of continental derivation, while the Middle Tardenois, which extended as far as the Isle of Man, points to Belgium. At the same time, the view thus taken of late Aurignacian industries must be kept in mind in considering sites which show a sequence of cultures, such as those described by Mr. A. L. Armstrong.

The study of types leads Mr. Clark to divide Britain into two provinces, of which Province *A* is characterised by the absence of the tranchet axe or pick, while the microliths are present both in the early non-geometric forms and in the later geometric forms, some of them of extremely small size. In Province *B*, the south-east of England, on the other hand, the tranchet axe is found, but the place of the geometric forms of Tardenois industry is taken by the still surviving non-geometric forms.

In the working out of the sequence and relation of the phases of Tardenois cultures, the investigations of Mr. F. Buckley in the Pennine chain are especially significant, although the whole chain has not been covered and his conclusions are drawn only from certain selected sites, such as Standedge Ridge, Yorks, where the whole chain narrows down to a single ridge, along which mesolithic man must have passed in avoiding the valleys. Various mesolithic sites under the peat have been excavated. These sites contain the relics of two distinct peoples or races of Tardenois folk. Of these one is known as the folk of the 'broad blade' industry, the other as the people of the 'narrow blade' industry. The implements of the former are predominantly of the non-geometric type and include many pointed blades, while among those of the latter are numerous small geometric tools. This people used open-air encampments and wandered freely over the hills; but the 'broad blade' folk travelled along the watershed ridge and erected huts or wigwams on their camping sites. The hearths have yielded wood remains, giving some data as to tree distribution in mesolithic times.

An important contribution to the discussion of mesolithic problems, comprehensive in its view, was made by Mr. A. L. Armstrong's account of his investigation of the Tardenois and pre-Tardenois cultures of north Lincolnshire in the light of evidence afforded by a number of sites in that area. Here a series of stratified sections and occupied sites exhibits a continuous sequence of industries, embracing the Upper Palæolithic and the whole of the Mesolithic periods. Mr. Armstrong has recently discovered Aurignacian flint implements in glacial gravels at Hardwick Hill, east of the Trent. These are heavily rolled, owing, it is suggested, to the wave action of an estuary or glacial lake, and point to the existence here of palæolithic man before the last glaciation—possibly a band of hunters who had penetrated the swamps and taken up their residence on the dry uplands of the Cliff Range and, probably, also on the Wolds. They appear to have inhabited this region through the last phases of the glacial epoch and to have remained until the appearance of mesolithic peoples, the Azilian and Tardenois. The latter eventually dominated Lincolnshire, according to the indications of a number of stratified sites.

Of these sites the earliest is a late-Developed Aurignacian (Creswellian) station, discovered by Mrs. E. H. Rudkin, and excavated in February last, on the western escarpment of the Lincolnshire cliff above Willoughton. At Sheffield's Hill, near Scunthorpe, a similar occupation site, but of later date, gives evidence of the final phase of the developed Aurignacian, upon which early Tardenoisian was imposed. At Risby Warren, Scunthorpe, where systematic researches have been carried out for eleven years, there is stratified evidence of occupation levels ranging from developed Aurignacian, which is quite free from Tardenois influence, to the earliest neolithic, full neolithic and bronze ages. The Tardenois culture is represented by several horizons and can be classified broadly as early and late. This site, Mr. Armstrong claims, in virtue of its abundance of stratified material and its numerous occupation zones, representing the whole of the Tardenois period, is to be regarded as the type station of Tardenois culture in England.

University and Educational Intelligence

WALES.—The University Court at its meeting on December 15 decided to award the degree of D.Sc. *honoris causa* to Prof. Francis Ernest Lloyd, professor of botany in McGill University, and Prof. Robert Robinson, Waynflete professor of organic chemistry in the University of Oxford.

THE Institute of Sociology, Le Play House, 65 Belgrave Road, London, S.W.1, has now been incorporated as a company limited by guarantee. This is the final step in a scheme for permanently establishing and endowing the Institute, which was initiated in 1920 through the generosity of the late Mr. and Mrs. Branford. Under an order of the Chancery Court, the whole of Mr. Victor Branford's estate, subject to the temporary reservation of a portion for the benefit of relatives, passes to the Institute. The present officers of the Institute are Dr. R. R. Marett (president), Rector of Exeter College, Oxford; Mr. C. H. Rigg (honorary treasurer), and Mr. A. J. Waldegrave (chairman of council).

Calendar of Nature Topics

January freeze-the-pot-by-the-fire

January, the coldest month of the year in England, is proverbially associated with snow and ice. In the French Revolutionary Calendar of 1793, the period from December 21 to January 19 was the month 'Nivôse' or 'snowy'. During the twentieth century, however, January has not lived up to its name, but has been much more open, mild and stormy, with few prolonged frosts. At Greenwich the mean January temperature during the decade 1921–30 was 41·3° F., more than 2° F. above the long-period normal and probably 5° or 6° higher than in some of the decades of the late eighteenth and early nineteenth centuries. This persistent period of mild winters has extended over the whole of western and central Europe; it is associated with a greatly increased frequency of south-westerly winds and may almost be regarded as a change of climate.

Life in the Southern Atlantic Ocean

"January 1—Wilson's petrels, two kinds of prion petrels, albatrosses and a bosun bird were observed to-day. Sun-fish (*Orthagoriscus mola*) were also seen; at 2.30 p.m. a boat was lowered to get one. After several ineffective attempts at harpooning we managed to stun one with shot. Davidson after a while drove the harpoon into the gills, and we then made fast to one of its fins and towed it to the ship. Three or four sucker-fish accompanied it to the boat, and on cutting the sun-fish up, one was discovered in the gills. A parasitic copepod (*Argulus*) was found externally, as well as a polyclad. There was also a parasitic copepod on the gills and a barnacle on the lip. In the intestines numerous tape-worms were found and another leech-like parasite. There was in all probability about 10 lbs. weight of tape-worms in the gut. Its weight by the dynamometer was half a ton. Several others were seen twice as large. Brown saw a globe-fish with a small fish attendant on it. *Salpa* were seen frequently floating past." From "Zoological Log of S.Y. *Scotia*", on January 1, 1903, in lat. 39° 01′ S.; long. 53° 40′ W.

The lethargy of the sun-fish has often been referred to. The individual mentioned above, now exhibited in the Royal Scottish Museum, Edinburgh, was regarded by its captors as a tiny specimen compared with others seen the same day "about the size of a small haystack", and of it they said, "Its stupidity was amazing; unable to swim faster than a boat could row, all it had to do to escape was to sink—and this they can do quite well,—but although struck by a harpoon a dozen times before one held, it made no attempt to escape. . . . When cut up it was easily seen why the first harpoons would not hold, as under the skin was a layer two or three inches thick of a hard cartilaginous material. The dissection was performed mainly with axes. The central nervous system was very interesting on account of its minute size relative to the body, the spinal cord being only about half an inch long and barely coming outside the cranial cavity. This degeneracy is doubtless correlated with the feeble musculature and swimming powers. Intelligence and mobility have become superfluous, the size and thick hide being sufficient protection against most enemies." From "The Voyage of the *Scotia*", by R. N. Rudmose Brown, R. C. Mossman, and J. H. Harvey Pirie.

Hurricanes of the Southern Hemisphere

January 7.—The greatest frequency of hurricanes or revolving storms in the southern hemisphere occurs about the second week in January, though they may be experienced at any time during the southern summer. Four areas are subject to these storms, the islands of Polynesia, especially the Samoa, Fiji and Tonga groups, the Coral Sea between Queensland and the Fiji Islands, the north-west coast of Australia and the South Indian Ocean between the Chagos Archipelago and Madagascar. The Australian storms are locally known as 'Willy-willies', and in addition to causing loss of shipping, frequently result in disastrous floods. The majority of the hurricanes in the southern hemisphere originate between lat. 5° and 15° S., travel at first towards west-south-west, recurve in about 20° S. and finally pass away to the south-east, decreasing rapidly in intensity.

"Furze or Gorse (*Ulex europæus*) flowering"

This record made by Gilbert White at Selborne on January 8 is a reminder of the winter activity of gorse which makes it an important item in the economy of the countryside. The closely cropped conical bushes, which in many places dot a pasture like old-fashioned bee-hives, are evidence of the part it plays in the winter food-supply of rabbits and sheep. Before roots were commonly available for the winter feeding of farm stock, gorse partly took their place: "The sowing of whins for feeding of cattle takes mightily about London just now [1725] . . . this improvement comes from Wales, where it has been practised these hundred years." In Scotland rough whins from waste ground were used in place of the more tender sown crop, and these had to be broken and pulped before being served to the cattle. The apparatus used was a cumbersome whin-mill, the essential part of which consisted of a huge stone roller dragged by an ox or a horse round a paved circuit, upon which the whins were laid. Remains of such whin-mills are still to be seen at occasional farmhouses in Scotland, although whins have long since dropped out of use. In the south of Ireland, however, on hillside farms where hay is scarce, whins are still used for feeding horses during the winter months. The seed is sown on spare ground, and the crop, cut in the following year, is passed through an ordinary chaff-cutter before being served.

The Hibernation of Frogs

In early January 1932, Francis B. Bent (as recorded in the *Observer*, May 1, 1932) emptied a pond and cleaned it out. The pond was ten to fifteen feet deep and the normal depth of water was four feet, but in the clay ooze at the bottom there were discovered thirty or forty frogs. In the same month H. C. Davies (*Field*, May 8, 1932) ran the water out of a small spring-fed pond in order to dig the mud out. In so doing he dug out, not an isolated frog, but dozens. "Their appearance was not attractive—discoloured and skinny—but all alive, though showing very little energy."

Although the older naturalists believed in the hibernation of frogs in winter in the mud of ponds, doubt has recently been thrown upon the possibility of survival of air-breathing, lung-possessed creatures in such circumstances. However, in the height of the mating season, when activity is not at its lowest, one has seen beneath the clear water of a pond mated frogs remain for long periods inactive on the bottom, and in face of such experiences as are related above it seems probable that in cold weather the lowering of activity in these cold-blooded animals reduces metabolism to so low a pitch that the oxygen required can be obtained by transpiration through the skin. The problem still to be solved in regard to cold-blooded hibernators, as P. A. Gorer has pointed out, lies in the physiological changes which enable the tissues of an adapted animal such as the common frog (*Rana temporaria*) to recover from cooling which is not excessive, while such recovery is impossible in unadapted animals.

Societies and Academies

LONDON

Royal Meteorological Society, Dec. 14. C. S. DURST: "The thermal balance of a water drop or ice particle suspended in the atmosphere." From the examination of the long wave radiation received and given out by a water drop or ice particle, it is shown that such a particle will lose heat if it is above a certain critical temperature and gain heat if it is below, from which it follows that if a particle exists in the stratosphere it will gain heat. It is assumed that the base of the stratosphere is saturated and consideration is given to the conditions under which particles could be formed. If a small air mass were raised in the stratosphere the particles formed in it would be melted in a very short time and the temperature of the air would once more be that of its surroundings, the entropy of the air having been increased in the process.—E. W. BLISS: The tabulation of world weather (5). (Discussion by Sir Gilbert Walker.) (*Mem. Roy. Meteor. Soc.*, 4, No. 36.) In order to form more definite ideas regarding the oscillations named the North Atlantic, the North Pacific, and the Southern, series of figures have been derived to express the variations of each, and from these have been obtained their relations with pressure, temperature, and rainfall over wide regions as well as the relations of the three oscillations with each other and with sunspots. The southern oscillation in the southern winter is extremely persistent, and its departure has a correlation coefficient of 0·84 with that of the following summer.—C. S. DURST: "The breakdown of steep wind gradients in inversions." On certain occasions when inversions have formed, a violent eddying arises, which is shown on an anemometer as an abrupt change in the type of trace. This change over occurs when the wind gradient becomes great. On the ground that the eddies formed in these circumstances are different in character from those formed with an adiabatic temperature gradient, a suggestion is put forward for the mechanism of the diurnal variation of wind.

DUBLIN

Royal Dublin Society, Nov. 22. J. H. J. POOLE: An investigation of the behaviour of neon discharge tubes in a flashing capacity circuit by means of a cathode ray oscillograph. The effects of leakage currents in the oscillograph were eliminated by using the oscillograph in conjunction with a valve anode resistance amplifier. For small shunting capacities the flashing may be extremely irregular, and quite considerable currents pass through the tube before the flash occurs. The presence of radium lowers the striking potential and, by decreasing the maximum dark current, increases the regularity of flashing. The effect of the shape of the electrodes has also been investigated. For concentric cylindrical electrodes, at the filling pressures used, the difference between the striking and extinction voltages is less when the inner cylinder is negative. H. M. FITZPATRICK: The trees of Ireland, native and introduced. A catalogue of the tree species growing in Ireland giving the dimensions attained by each in different parts of the country with, in the case of exotics, an account of their natural distribution and introduction into cultivation. 150 broad-leaved and 215 coniferous trees are recorded. G. T. PYNE and J. J. RYAN: The colloidal calcium phosphate of milk. Some samples of milk out of a large number tested developed a marked alkalinity to phenolphthalein on addition of oxalate. As the wheys prepared from the same milks did not do so, it appeared that the alkalinity must arise from the interaction of the (potassium) oxalate with the casein calcium phosphate complex of milk, presumably owing to the conversion of insoluble tri-calcium phosphate into the strongly alkaline tri-basic potassium salt. The amounts of tricalcic phosphate required to account for the observed alkalinities approximated to those usually accepted for the entire colloidal phosphate of milk, suggesting that the greater part of this colloid must consist of the tribasic salt. The bulk of the casein calcium phosphate complex was removed by prolonged high speed centrifuging from two very different types of milk (as regards their reaction with oxalate) and submitted to analysis. The results appeared to show that the bulk of the colloid in each case consisted of tricalcium phosphate, and that the variations in the behaviour of different samples to oxalate was thus connected with the relative quantity of the colloid present rather than with variations in its composition.

PARIS

Academy of Sciences: Nov. 14. CH. MAURAIN and J. DEVAUX: Electrical conductivity and atmospheric condensation nuclei during a voyage to Greenland. There is a general resemblance between the electrical conductivity of the air in the polar regions and that on mountains at high altitude, possibly due to the purity of the atmosphere and the dryness. The measurements were too few to enable any deductions to be drawn as to the effects of the meteorological conditions. MARIN MOLLIARD: Aseptic tuberisation and morphological characters resulting from the action of saccharine food on the onion, *Allium cepa*. E. MATHIAS: Death by the return stroke (lightning). J. CANTACUZÈNE and A. TCHEKIRIAN: The presence of vanadium in certain tunicates. Vanadium has been found in nine species of tunicates: the proportion is higher in young animals than in adults. POTRON: The Riemann spaces admitting a group of isometric transformations with $n\ (n+1)/2$ parameters. MARCEL BRELOT: The study of the point singularities of subharmonic functions. PIERRE HUMBERT: Bessel-integral functions. D. POMPEIU: A theorem, analogous with that of Rouché, relative to the zeros of holomorph functions. NICOLAS APRAXINE: A calculating machine worked electrically. B. GALERKIN:

The general solution of the problem of elastic equilibrium of a hollow circular cylinder and of a part of the cylinder. R. de Fleury, H. Portier and S. Benmakrouha : The comparative and reciprocal influences of individual values, for each alloy and for each state of the alloy, of the modulus of elasticity, the elastic limit and the density on the dimensions of beams and elements of framework under bending. Louis de Broglie : The electromagnetic field of the light wave. L. Goldstein : The quantum theory of the diffusion of electrons. André Marcelin and D. G. Dervichian : The direct measurement of superficial pressure of superficial solutions formed by soluble substances. P. Rouard : The reflecting power of metals in very thin plates. The reflecting power varies with the thickness of the film, passing through a minimum depending on the wave-length of the light. Ch. Bedel : The temperature coefficient of the electrical resistance of silicon and a thermoelectric phenomenon of unipolar substances. A. Sanfourche and B. Focet : The calcium salt of a complex ferrophosphoric acid. F. Gallais : Potassium iodomercurate. Léon Jacqué : The alteration of steels by hydrogen. The modification of the micrographic structure of steel submitted to the action of hydrogen under pressure and at temperatures between 400° and 700° C., appears to be the result of two simultaneous phenomena : the elimination of the carbon of the steel by the hydrogen, and a diffusion of the carbon from the unaltered regions towards the decarbonised regions. The process is a reversed cementation. The change depends on the composition of the steel, chrome-nickel steels, for example, being less altered under the same conditions. M. Lesbre : An imperfect silver-guanidine complex. R. Levaillant : The action of acid chlorides on orthoformic esters. The preparation of symmetrical esters of sulphuric acid. The reaction $CCl_3.COCl + HC(OC_2H_5)_3 = CCl_3.CO_2C_2H_5 + C_2H_5Cl + HCO_2C_2H_5$ gives a 90 per cent yield of the ethyl trichloracetate. The reaction is a general one, and can be extended to the sulphonchlorides. G. Darzens : A new method of glycidic synthesis of aldehydes. Lespieau and Wiemann : The synthesis of allodulcite. Y. Milon : The antiquity of the depression of the gulf of Morbihan. G. Dubar and H. Termier : The facies of the Lias underlying the Toarcian in the Moroccan middle Atlas. J. Gauzit : An attempt at the estimation of atmospheric ozone by visual photometry. The method detailed, which has the advantage over other methods in use of taking less time, measures the thickness of the ozone layer in the atmosphere with an uncertainty of less than ten per cent. Ph. Joyet-Lavergne : Oxidising power, chondriome and cytoplasmic sexualisation in the Fungi. J. Beauverie and Mlle. S. Monchal : The life of green plants in a confined atmosphere. Plants contained in glass vessels, with moist earth, and sealed with paraffin wax, can live and grow for several years. Examples are given of plants which have remained in good condition for three or four years thus sealed up. Michel Gračanin : Contribution to the study of the relation between transpiration and the resorption of ions. Marc Simonet : New interspecific hybrids in *Iris* and their cytological study. Armand Dehorne : New observations on the asexual multiplication of an annelid of the genus *Dodecaceria*. Etienne Rabaud and L. Verrier : The evacuation of the gases from the air bladder and the working of the pneumatic canal. Paul Wintrebert : The two phases of segmentation and the subdivision theory in amphibians.

Forthcoming Events

Monday, Jan. 9

Royal Geographical Society, at 8.30.—B. Roberts : "The Cambridge Expedition to Vatna-Jökull, 1932".

Tuesday, Jan. 10

Royal Anthropological Institute, at 8.30.—Dr. N. Gordon Munro : "The Ainu Bear Ceremony" (Film).

Thursday, Jan. 12

King's College, London, at 5.—Prof. R. J. S. McDowall : "The Integration of the Circulation" (succeeding lectures on Jan. 19, 26 and Feb. 2).

Gold in Kenya and Native Reserves

AS has happened on more than one occasion in the past, proposals gravely affecting the future of the native population of a British dependency have almost reached the point of being given effect before they have attracted public attention. In order that the gold recently discovered in Kenya may be worked, any land in the occupation of natives required for the leasing of mining rights is to be excluded from native reserves and the occupants dispossessed. To make this possible, amendments to the Native Lands Trust Ordinance have been drafted and embodied in a Bill which on December 21 passed its second reading in the Legislative Council of Kenya Colony.

When questioned in the House of Commons on December 20, the Secretary of State for the Colonies stated that the amendments had received his approval as an interim measure to facilitate the granting of leases and to remove any immediate difficulties which might retard the development of valuable minerals, property in which was vested in the Crown. Notwithstanding his assurance that he had satisfied himself that the interests of the natives would be fully safeguarded, it is impossible to receive this announcement without a feeling of unease. No information has as yet been made public to indicate the manner in which these safeguards will be made operative, in view of the conditions affecting native life in Kenya.

The amendments to the Native Lands Trust Ordinance, as they stand in the Bill, and as they have been explained by the Colonial Secretary in the House of Commons, will appear to the native as a breach of trust. They abrogate specific undertakings made on the part of the British Government. On their face they do not meet the needs of the situation which, inevitably, will arise.

What is the nature of these proposals? Briefly, they are that land may temporarily be excluded from a native reserve for the purpose of granting leases for the development of valuable minerals, and that in such cases compensation may be made by money payment, instead of being given in the form of land. The Colonial Secretary added that where compensation was given in the form of a money payment, it would be at least equal to what would have been given to a white settler; and the Chief Native Commissioner of Kenya stated that no native would be "a penny the worse" for the proposals.

In dealing with a white settler this attitude would be just, and the treatment meted out to him would, in all probability, be generous. In dealing with the natives the same treatment is neither just nor expedient. It deliberately sets aside the lessons which have been taught by scientific study of native institutions, of native modes of life and of native ways of thought.

The Native Lands Trust Ordinance is to the natives of Kenya their Magna Charta. It ensures to them their rights in their lands. It sets aside land as a native reserve; and it enacts that when, for the direct benefit of the native, land is taken from the native reserve, compensation shall be made by the addition of alternative land of an equal area. This is no mere concession to sentiment. It is a recognition that land is a vital factor in tribal life. At the same time, in setting aside tracts of land in exclusive native occupation, it provides a measure of protection for native institutions against the disintegrating impact of white civilisation.

The economic, social and religious life of an East African tribe or family group, speaking generally, is bound up with its land. Their only form of wealth is cattle, of which the importance is fundamental in the regulation of marriage and, indirectly, of all the social ramifications which issue therefrom, inheritance, status and the like. The group lives normally on the produce of its gardens and cultivated land. Land is a tribal possession, and its tenure by smaller groups determines relation to the chief, by whom it is allotted as the head of the tribe. Hence land is not only an essential for the subsistence of the tribe by pasture and tillage but also the basis of tribal solidarity. On the other hand, the spiritual relations and associations with the land are even more binding. It is the home of the ancestors, not of the dead, but of living spirits, and upon it grow the sacred trees at which the people from time immemorial have made offering to spirits, and of which the sanctity is such that damage to the least of their twigs may bring untold misfortune on the tribe.

Differences exist, naturally, from group to group; but as generally outlined, these are the factors, material and spiritual, with which any measure for dispossession will have to cope. It is improbable that any considerable number of the dispossessed natives will be settled on other land; and they can be given no security of tenure. This has been made plain. It has been said that they will not like being settled on land from which they can be ejected. It goes deeper than that. The tribes will have lost their sovereignty, to use the jurist's term. Their tribal status will have gone and they will see themselves, like other East African tribes settled on lands in the possession of others, sinking to serfdom.

On the other hand, those for whom no land is available, to whom a money payment—into a tribal fund—will be made, will receive a form of compensation they do not understand and for which they will have little or no legitimate use. They have no conception of either the employment or the value of money as an economic factor. The example of those who have gained experience of European currency by wage-earning proffers a warning. The money, usually, has been squandered and wasted, while its expenditure, by giving the individual an exaggerated idea of his importance, has loosened the bonds of tribal discipline and respect for chiefs and elders. As for the tribal fund, the experience of America, when the discovery of oil on a reserve has enriched an Indian tribe, has furnished an example of the difficulty of regulating expenditure to the tribal good. The money has been wasted and frittered away.

In introducing the amendments in the legislature on the occasion of the second reading of the Bill, the Chief Native Commissioner said that he feared that the amendments would be "unpopular" among the natives, and admitted that it would be necessary "to hurt their feelings, wound their susceptibilities, and in some cases violate their most cherished and sacred traditions by moving them from their land". Thus it is patent that the Administration has chosen this course of action, not through ignorance of facts, which anthropological science might have made available, but deliberately and with premeditation. It has elected to set aside the consideration of matters which are within the knowledge of, at least, the chief officer to whom the care of the natives has been entrusted and upon whom the responsibility of introducing and explaining the proposals has been laid.

It would seem a not improbable contingency, especially in view of the religious susceptibilities of the tribes, that the proposals, if carried into effect, will cause serious tribal unrest. The extent to which that unrest may spread is impossible to forecast, even if it is confined to the gold-bearing area, for this the authorities are at present unable to delimit. But quite apart from the possibility of tribal disturbance, the very serious problem arises of the future of the dispossessed natives, deprived as they will be of their only means of livelihood. Divorced from the land, tribal organisation and tribal discipline will disappear. Members of the tribe will become 'landless men', whose only recourse will be labour in the mines—had the Administration this in view as a possibility?—or to drift to the towns and European employment and, thoroughly detribalised, to add to the gravity of the problem, already grave, of the native rabble, saturated with vice, which threatens to become a menace to the European.

Much hangs on the decision to dispossess the native of his land. It is not a question that can be settled by a simple balancing of immediate gains and losses. The native cannot, like a white man, be compensated for disturbance by a money payment, however generous; and even if the exclusion of land were really to be temporary, in the sense that it lasted for a very brief duration of time—a matter that no one can judge at present—when once the native has been divorced from his land, the break-up of tribal institutions and the consequent detriment to morale are irrevocable. Among other tribes who remain undisturbed, confidence in the integrity and singleness of purpose of the Administration in dealing with native affairs will have been badly shaken.

Of those who have followed closely the trend in the development of the African in the years which have followed the War, a majority are convinced that for the safety of the European and the well-being of the African himself, progress must come through the gradual development of native institutions in harmony with native ways of thought; that safety lies in the support, the moulding and the building up of native ways of life and thought and not in violently breaking them down.

When, a few years ago, in Australia a large tract of land was set aside as a native reserve, the two States concerned concurred in forbidding prospecting for minerals on native lands. In Kenya an immediate and easily won prosperity may be dearly bought at the cost of an incalculable addition to the native problem and the weakening of the stock, physically and morally, from which the future population of the country will be drawn. Is it possible to reconcile the action now contemplated with the spirit, much less the letter, of the famous White Paper which enjoined that the interests of the native should be paramount?

Spectroscopic Analysis by X-Rays

Chemical Analysis by X-Rays and Its Applications. By Prof. Georg von Hevesy. (The George Fisher Baker Non-Resident Lectureship in Chemistry at Cornell University.) Pp. xi + 333 + 28 plates. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1932.) 3 dollars.

FOR a long time the line spectrum of an element has been used as a means for its identification and, more recently, spectroscopic methods have been developed not only for qualitative but also for quantitative chemical analysis. If the optical spectrum has been found so useful in the practical problems of analysis, it is only to be expected that the X-ray spectrum should prove capable of being similarly employed. When the nature and method of excitation of the optical and the X-ray spectrum are compared, it becomes clear that the latter has much to commend it. In the first place, the X-ray spectrum is much less complex and remains practically unaltered by changes in external conditions. Again, all the elements have similar spectra which differ from one another only in a regular and continuous decrease in the wave-lengths of corresponding lines as the atomic number increases. It is thus possible to predict with accuracy the X-ray spectrum of an element. Further, in order to excite the optical line spectrum, it is necessary to vaporise the material, while the X-ray lines can be obtained without the destruction of the material under investigation.

The important part which X-ray spectroscopy was destined to play in chemical analysis was foreshadowed by one of the deductions which Moseley made from his earliest measurements of X-ray wave-lengths. Even from the incomplete data at his disposal, he could and did deduce the number of elements between hydrogen and uranium which still remained to be discovered. Since then, several of these have been found and X-ray methods have played an important part in their discovery and identification.

Following on the pioneer work of Moseley, the comprehensive and highly accurate work of Siegbahn and his school has given us a very complete knowledge of the X-ray wave-lengths characteristic of the various elements. Apart from the fundamental importance of such measurements in connexion with the problems of atomic physics, they provide all the necessary data for the application of X-ray methods to the problems of chemical analysis. The importance of X-ray spectra in the solution of such problems is certainly more than sufficient to justify the publication of a book devoted to the subject and it would have been difficult to find anyone better qualified to write such an account than Prof. Hevesy, who has contributed so much to its development.

The earlier chapters are devoted to a discussion of the nature and production of X-ray spectra and contain an admirable account of the various ways in which such spectra may be excited and measured. This section, besides containing the description of all the necessary apparatus and methods, is full of information which will prove invaluable to the actual worker in this subject and is not readily accessible elsewhere. Naturally, for qualitative analysis, the method is exceedingly simple; the mere occurrence of lines corresponding to the characteristic wave-lengths of an element imply the existence of that element and a very rough quantitative analysis is obtained by a comparison of the intensities of the lines of the various elements. For many purposes, however, such an analysis is insufficient and accurate quantitative results are essential. It is in obtaining such results that the unsuspecting worker is liable to fail, unless he is aware of the many pitfalls and how these may be avoided by the use of a proper technique. These difficulties are discussed in detail by Prof. Hevesy and full accounts are given of methods which enable an accurate quantitative analysis to be made even when the element in question occurs only in very small quantities. The actual sensitivity of the method depends upon the nature of the material under investigation. In the analysis of minerals, it is possible to determine a concentration of about one part in 10,000, while in more favourable circumstances such as, for example, the determination of titanium in iron, a much higher sensitivity is obtained.

Of particular interest is Prof. Hevesy's description of analysis as carried out by the use of secondary X-radiation. Instead of mounting the material on the anticathode of the X-ray tube and analysing the radiation emitted by it as a result of electron bombardment, the material is mounted inside the tube in such a way that it is not bombarded by electrons but is subject to an intense X-radiation from a suitable anticathode. This method involves longer exposures but has the very great advantage that it avoids the heating up of the material and its possible change in constitution as a result of the evaporation of the more volatile constituents.

The remaining sections of the book deal with applications to special problems. As typical of these a full account is given of the discovery of hafnium and of its properties. This section is all the more interesting since it comes directly from one to whom the discovery was largely due. Incidentally, detailed accounts of the chemical properties and the optical spectrum of the element are included. The last section deals with the chemical constitution of the earth and contains a discussion of the relative abundance of the various elements in the earth and in the sun and stars. This may appear to be somewhat outside the natural scope of such a volume, but in actual fact X-rays have proved of considerable value in the determination of the relative abundance of the rarer elements in rocks and meteorites. Of special interest is the use of X-ray analysis to estimate the age of rocks by a determination of the uranium, thorium and lead content.

This is a book alike for the specialist and for the general reader. The specialist will find it full of instructive detail and most useful and comprehensive tables, and indispensable for reference purposes. The general reader will find a very readable account of one of the most interesting developments of the discovery of X-rays and much other information besides. The many excellent illustrations add considerably to its attractiveness.

Medical Biography

(1) *Osler and other Papers.* By Prof. W. S. Thayer. Pp. vi + 386. (Baltimore, Md.; The Johns Hopkins Press; London: Oxford University Press, 1931.) 21*s*. 6*d*.

(2) *The Genius of Louis Pasteur.* By Piers Compton. Pp. ix + 361 + 8 plates. (London: Alexander Ouseley, Ltd.; New York: The Macmillan Co., n.d.). 12*s*. 6*d*.

(3) *Ronald Ross: Discoverer and Creator.* By R. L. Mégroz. Pp. 282 + 4 plates. (London: George Allen and Unwin, Ltd., 1931.) 10*s*. 6*d*. net.

OF these three books, the first, which is written by a medical man, will appeal most to members of his profession, while the other two, which are the work of laymen, are more suited for the general reader.

(1) Dr. W. S. Thayer, formerly professor of medicine in the Johns Hopkins University and a former president of the American Medical Association, collected in a single volume a number of addresses and papers mainly of a biographical nature which he had delivered or published at intervals during his professional or university life. Five of them, which are devoted to the late Sir William Osler in his aspects as teacher, man and booklover, are undoubtedly the most interesting part of the book, in view of the close friendship that existed between Osler and the author for so many years.

The centenary of the publication of Laennec's classical work on auscultation which appeared in 1819 is celebrated by an address which Thayer delivered before the Canadian Medical Association at Quebec on June 26, 1919. After describing Laennec's contributions to medicine, Thayer deplored the present tendency in Canada and the United States to neglect clinical examination as taught by Laennec and Auenbrugger, the inventor of the method of percussion, in favour of laboratory reports.

Pasteur is commemorated by an address on his contributions to medicine and humanity which Thayer delivered at the Sorbonne on May 22, 1927, on the occasion of a meeting organised by the American Committee for the Commemoration of the Centenary of Pasteur's Birth.

Attention should also be directed to the address on the life and work of Richard Bright given at Guy's Hospital on July 8, 1927, on the occasion of the centenary of the publication of the first volume of Bright's medical cases which contains the description of the disease bearing his name.

The other biographical studies are connected with Reginald Heber Fitz of Boston, U.S.A., who in 1886 gave the first full account of the now familiar condition which he named appendicitis; John Howland of Baltimore, an eminent specialist in children's diseases; and Cotton Mather, the seventeenth century Congregationalist minister of Boston, elected F.R.S. in 1713, who among his unpublished manuscripts left a work entitled "The Angel of Bethesda: an Essay upon the Common Maladies of Mankind" as well as a small volume containing rules of health drawn up for the use of candidates for the ministry. Copious extracts from these two curious works are given.

The many friends and admirers of the late Dr. Thayer will be grateful for this collection of his writings, many of which would be otherwise inaccessible.

(2) In his work on Pasteur, whom he describes as "the scientist of the heart", Mr. Piers Compton gives a clear and sympathetic account of the life and achievements of this great Frenchman, relating in succession his studies in crystallography culminating in his discovery of the molecular dissymmetry of tartaric acid; his work on fermentation, and particularly his paper on lactic fermentation, which was the foundation of bacteriology; his overthrow of the doctrine of spontaneous generation; his preservation of the silkworm industry of France by discovery of the nature of the disease and its prevention; his studies in connexion with the French wine and beer industries; his development of the germ theory and particularly its application to surgery; and his work on anthrax and rabies.

Special emphasis is laid on the difficulties with which Pasteur had to contend, including not only illness in himself and his family but also the opposition which he first encountered from the medical faculty particularly in the Paris Academy of Medicine, of which he was elected a member, although he had never obtained a medical qualification or been through the ordinary medical curriculum.

(3) The biography of the late Sir Ronald Ross by Mr. R. L. Mégroz, who has dedicated his book to "all true hero worshippers", is divided into two parts, the first dealing with Ross's life and scientific achievements and the second with his literary work. Mr. Mégroz defends this division first by the claim that he is specially qualified to criticise literary work and secondly by the charge that Ross's literary work has been unduly neglected.

In addition to the account of Ross's life and work particularly in relation to the discovery of the transmission of the malarial organism by the mosquito, the first part contains a chapter in which the writer acknowledges his indebtedness to Mr. Walter Stott, formerly secretary of the Liverpool Mathematical Society, and Mr. J. T. Combridge, of King's College, London, for their exposition of Ross's work in mathematics and its application to epidemiology.

In the second part high praise is bestowed on Ross's work as a satirist, critic, dramatist, lyric, poet and novelist, numerous extracts being given from this comparatively unknown portion of his writings.

Appendices contain a bibliography of Ross's scientific and belletristic writings as well as lists of his honours and awards.

Fish and Fishing

(1) *The Flyfisher and the Trout's Point of View: New Light on Flyfishing Theory and Practice.* By Col. E. W. Harding. Pp. 208 + 11 plates. (London: Seeley, Service and Co. Ltd., 1931.) 21*s.* net.

(2) *Salmon Fishing.* By Eric Taverner. With Contributions by G. M. L. La Branche, Eric Parker, W. J. M. Menzies, J. A. Rennie, A. H. E. Wood, Wyndham Forbes, Thomas Rook and Alban Bacon. (The Lonsdale Library of Sports, Games and Pastimes, Vol. 10.) Pp. vi + 472 + 111 plates. (London: Seeley, Service and Co., Ltd., 1931.) 25*s.* net.

(3) *Salmon Hatching and Salmon Migrations: being the Buckland Lectures for 1930.* By W. L. Calderwood. Pp. 95 + 4 plates. (London: Edward Arnold and Co., 1931.) 4*s.* 6*d.* net.

(4) *Silver: the Life Story of an Atlantic Salmon.* By R. L. Haig-Brown. Pp. 96. (London: A. and C. Black, Ltd., 1931.) 3*s.* 6*d.* net.

(5) *The Life of the Sea Trout, especially in Scottish Waters: with Chapters on the Reading and Measuring of Scales.* By G. Herbert Nall. Pp. 335 + 94 plates. (London: Seeley, Service and Co., Ltd., 1930.) 21*s.* net.

(1) THE rules of fly-fishing are largely empirical and although the dry-fly purist is often no mean entomologist, the immediate aim of an angler is to present a fly to a fish as simply and as unobtrusively as he can; if he succeeds, he seldom worries about the fundamental principles involved, and is content to be frankly anthropomorphic in his outlook to the whole of the piscine world. Seldom, if ever, does an angler consider the point of view of the fish.

Some knowledge of the problems presented by under-water vision we owe to the fascinating work of Dr. Francis Ward. Col. Harding's book develops this theme and is primarily of interest to anglers. Avoiding all technicalities with commendable care, the author shows by a series of simple diagrams how the phenomena of refraction and total reflection influence the rays which reach the eye of the fish and there give an image which is quite unlike that which most anglers would imagine to be the case. The application of these principles is chiefly concerned with problems peculiar to fly-fishing, but they deserve the careful attention of all who are interested in life in surface waters.

Some of Col. Harding's conclusions will probably provoke criticism, for anglers are notoriously sceptical of innovation. From a scientific point of view, the main arguments are convincing although they raise extremely difficult problems. The reactions of a fish to its visual environment will not only depend upon the optical image which falls on the retina of the eye but also upon how far the fish's sensations from such an image are comparable to our own; the reduced and distorted image of an angler on the bank may induce a sensation much more acute than it would in the human brain. If an angler is to be a physicist and a physiologist, must he not also be a psychologist? The prospect may be a little terrifying but Col. Harding's book is an extremely stimulating contribution to literature and will give pleasure to all who are interested in fish or fishing.

(2) Mr. Taverner's book on salmon fishing forms a natural sequel to his previous volume (also in the Lonsdale series), which was devoted to the trout. The present work is worthy of its author and worthy of the series in which it appears. The author is an expert and a scholar, but he also knows how to impart his knowledge to those less skilful than himself. For this reason, Mr. Taverner's book can freely be recommended to all who can afford to have even a remote interest in salmon fishing.

The literature of angling is outrageously large and it is swelled by works which have, at best, a transitory value, but the present work is in quite a different category, for the author has taken the pains to impart his knowledge in such a way that experts and beginners can read his pages with both profit and pleasure. The book covers every aspect of salmon fishing and every stage of the salmon's life from the moment the egg is laid until the adult fish lies, like a bar of silver, at the angler's feet. Mr. Taverner has consulted fellow experts and with real ability he has expressed their wisdom in 450 pages every one of which gives a thrill of interest and has its value. The book is beautifully illustrated by half-tone figures and by numerous useful diagrams.

Both author and publishers are to be heartily congratulated on their work and a perusal of the ordinary edition makes one envious of those who can afford the edition *de luxe*. It is just a little unfortunate that such an admirable book should not have had a rather more attractive page, the margins of which are narrow while the type is none too clear—but such remarks border on captious criticism. It is a thoroughly good book.

(3) Dr. Calderwood's little book is a small but scholarly production. It gives in a condensed but readable form the conclusions to be drawn from the important work done recently in Canada and other places on the effect of stocking rivers with fry which have been reared artificially in hatcheries. The facts show fairly clearly that the rate of increase in the number of 'migrating' fish derived from a standard number of parent fish can be definitely increased by hatchery methods. In all cases, however, the percentage mortality of fry is extremely high ; hence, if hatcheries are to effect any serious increase in the stock of mature fish, they must be established on a very large scale.

Dr. Calderwood also gives an interesting account of what little is known of the migrations of salmon in the sea, and he provides an interesting map. At the end of the book, the author describes a record leap of a salmon at the falls on the River Orrin, in Ross-shire—a leap of eleven feet and four inches.

(4) "Silver" was an Atlantic salmon and the history of his life is told as a bed-time story for children. The author tells us that he has tried to make it interesting and at the same time tried to keep to the truth about salmon and their ways. Those who read this book will readily forgive any digression—if such there be—from strict and academic truth. The story is written in simple yet graceful language and the theme is worked out from beginning to end with real insight and outstanding ability. Those who feel that the teaching of Nature can impress upon a child's mind a healthy outlook on life and on death, will appreciate this book and will read the story of "Silver" and his mate with keen delight.

Mr. Haig-Brown has written a book which will rank highly as a permanent contribution to literature. It is to be hoped that it will receive the wide circulation which it undoubtedly deserves.

(5) Although the sea-trout is perhaps the most attractive of our migratory fish, its life-history is seldom familiar to anglers or to biologists. For many years Mr. Nall has devoted his attention to this fascinating and important problem, and the present book represents a summary of his work and an exposition of his views. It is, as the author says, an attempt to review his own work in perspective. The whole story is admittedly incomplete, but Mr. Nall has performed a real service to biology by putting into book form a series of data which are not only inaccessible to many ordinary people, but also form a solid foundation for future work.

The opening chapters deal with the technical problems inherent to all such investigations, and the critical analysis to which Mr. Nall subjects his own methods of observation inspires a confidence in his ability to interpret scales in terms of age and life-history. In Chap. vi an interesting contribution is made to the vexed problem of the systematic relationship between the sea-trout and the brown trout. Systematists usually deny any specific differentiation between the two forms, in view of the absence of all significant structural differences. To this view Mr. Nall gives qualified support, but he takes a wider—and a better view—of the essential criterion of a species. He is satisfied that there is a diversity of habit or physiological specificity to each type as striking as are the diversities of structure which satisfy the usual systematic requirements. These diversities of habit ensure that the two forms "keep apart on the spawning beds" and breed true. Behind him, Mr. Nall will find a solid body of opinion from those whose knowledge is based on their observations as anglers. That the two 'species' are closely related is obvious, and there can be little doubt that the migratory form is the more primitive of the two.

Among the perplexing problems offered by the sea-trout are those concerned with the factors responsible for the marked variation in the rate of growth and in the habits of fish taken in different localities. These factors are highly complex and only very extensive and reliable data will enable us to form an adequate estimate of the rôle which is played by each environmental factor. As yet, such data are clearly wanting and consequently the account given by Mr. Nall is of peculiar value. Unless the reader is very familiar with the remoter districts of the British Isles, this section of the book could be improved by the addition of a map. Apart from this slight omission, the book is well illustrated, and the half-tone illustrations are both beautiful and instructive.

Mr. Nall covers every aspect of the fish's life, and raises many interesting problems of scientific and economic importance. How far do sea-trout migrate away from coastal waters ? In many cases (for example, Beauly Firth fish), they apparently stay comparatively close to the shore, but, in other cases, journeys of two hundred miles do not appear to be uncommon. Problems of this type offer full scope for future work—and it is hoped that the publication of this book will help to provide an adequate solution. The author handles his data on growth and maturity in a rather depressingly orthodox manner, but the facts are there for all who care to analyse them differently. The whole book is a mine of information and it is a book for the specialist; at the same time it should be read by all anglers who know and appreciate the sea-trout.

In his introduction, Mr. Nall explains that he is not and never has been a member of the Fishery Board for Scotland; it is fortunate that at least one of the fishery boards of Great Britain has the ability to attract and to keep the voluntary services of an efficient and enthusiastic colleague.

Short Reviews

Education for Trades and Industries: a Historical Survey. By C. T. Millis. Pp. 164. (London: Edward Arnold and Co., 1932.) 6*s*. net.

MR. C. T. MILLIS has performed a service in bringing together in this little book much information relating to the early history of the development of technical training for apprentices and craftsmen in various trades and industries. Himself a pioneer in this sphere of work, he has been able to place on record much that might otherwise have been lost. Those technical educationists of a later generation, reading of the struggles of their predecessors to provide for industry a mentally and manually competent personnel, will not fail to realise the debt owing both by themselves and by industry to these earlier workers. Nor will they omit from their list of benefactors many of the individual City Livery Companies and the City and Guilds of London Institute.

Mr. Millis deals in separate chapters with some eighteen of the most important trades; and there is also a short chapter devoted to technical education for women. An account is given in each case of the first classes to be formed and of the development that has taken place up to the present day. Perhaps an undue prominence has been given to the names of those who were primarily concerned with metropolitan training schemes; for the remarkable extension of technical education in the industrial north has not been brought about without its own pioneers. Surely, for example, the name of the late Mr. J. H. Reynolds, one of the greatest and most far-seeing of all the early technical educationists, deserves more than a single passing reference, and that under the heading of photo-engraving and lithography.

The author has drawn largely and rightly upon his own personal experience: this, while adding to the interest of the book, has resulted in a picture with London high-lights and the provinces somewhat in the shade. A completely satisfactory history of education for the trades and industries of Great Britain has, indeed, yet to be written. Meanwhile, Mr. Millis's book should be read by all who are interested in the development of craft training.

The Form and Properties of Crystals: an Introduction to the Study of Minerals and the Use of the Petrological Microscope. By A. B. Dale. Pp. x + 186. (Cambridge: At the University Press, 1932.) 6*s*. net.

IN this small volume Miss Dale has endeavoured to provide the minimum amount of crystallography and optics necessary for students whose main interests are petrological. It is a difficult task at best, but on the assumption that traditional lines are to be followed, the general scheme may be commended. The author has evidently been at pains to write simply.

The chapter dealing with stereographic projections contains a number of straightforward examples worked through in detail, which should help in mastering what is to many a forbidding subject. Unfortunately, however, the book is somewhat marred by a number of mistakes. The treatment of refractive indices is not very satisfactory, and the reference in the text to the chart of birefringences inverts ordinates and abscissæ. Fig. 117 and its context provide a puzzle; the reviewer looked long and carefully at these without understanding anything at all. The customary phrase 'convergent polarised light' is not a happy one at the best of times, and although students will probably manage to obtain an interference figure by following the appropriate directions, they will be well advised to be wary of interpreting what they see in the light of this illustration.

F. I. G. R.

Methods in Plant Histology. By Prof. Charles J. Chamberlain. Fifth revised edition. Pp. xiv + 416. (Chicago: University of Chicago Press; London: Cambridge University Press, 1932). 18*s*. net.

THIS, the latest edition of Prof. Chamberlain's book, needs little introduction to workers in a botanical laboratory. The changes are many and important, amounting almost to a re-writing. The new chapter on "Illustrations for Publication" will prove helpful to many research workers and the mention of a section on "Movie Photomicrographs" will serve to indicate how the different editions march with the times. Directions for collecting, fixing, dehydrating and staining material have been improved and amplified and refinements of technique are detailed, which make it easy to obtain sections as thin as 2 or 3 microns, while thinner sections down to a thickness of 0·5 micron can be made. Prof. Chamberlain's hint as to the possible appearance of a microscope of such magnifying power that no section thicker than 1 μ is permissible, is rather intriguing and will demand further improvements in histological technique along these lines. The amplifications noted have involved no curtailment of the sections dealing with the collecting and growing of all types of laboratory material and with the application of the principles of fixing and staining in the study of each group of plants—these sections constitute the second part of the book as in the earlier editions.

N. F.

Caratteristiche dei sistemi differenziali e propagazione ondosa. Per Tullio Levi-Civita. Lezioni raccolte dal Dott. G. Lampariello. (Attualità Scientifiche, N. 41.) Pp. vii + 110. (Bologna: Nicola Zanichelli, 1931.) 15 lire.

THIS little book is founded on a course of lectures, given by the author at Rome in 1930–31, on the theory of characteristics of partial differential equations and their applications (following the methods originated by L'Hugoniot and developed by Hadamard) to wave motion in acoustics, elasticity, optics, electromagnetism and other branches of physics. It opens by recalling some existence theorems concerning partial differential equations. The characteristics are introduced as the loci of singular points where these theorems break down. We then pass on to the consideration of wave motion, and wave surfaces prove to be closely connected with characteristics. The most interesting part of the book is the concluding section, which deals with the wave-particle dualism of modern physics according to de Broglie. An account is given of the recent dynamical-optical work of Persico, which aims at making Schrödinger's wave equation plausible, and a tantalisingly brief reference is added concerning Racah's use (in 1931) of the principles expounded in this book to obtain a justification of Heisenberg's principle of indeterminacy. Most readers will probably wish for a fuller account of the new developments so briefly mentioned here.

H. T. H. P.

The Grey Squirrel: the Introduction and Spread of the American Grey Squirrel in the British Isles, its Habits, Food and Relations with the Native Fauna of the Country. By A. D. Middleton. Pp. viii + 107 + 8 plates. (London: Sidgwick and Jackson, Ltd., 1931.) 4*s*. 6*d*. net.

THE grey squirrel has become almost as valuable as the sea-serpent to correspondents of British newspapers, and genuine inquirers who are distraught between the assertions of the 'pro-squirrelites' and the 'anti-squirrelites' will be glad to have this authoritative work at hand. It touches upon the life of the grey squirrel in its native home in eastern and central North America, but its real purpose is to describe the invader in the land it has invaded with such success that from one centre (out of about thirty) it has spread over 1,350 square miles, and that, in thirty years. The food and habits, the much discussed relations with the native red squirrel and other animals, and the economic aspects of the pest are dealt with thoroughly, the conclusion being reached that three main counts have been proved against it—damage to forests by peeling bark and destroying shoots, destruction of agricultural and garden produce, including fruit, and destruction of birds' eggs and young. Suggestions are made for the destruction of grey squirrels, but the seriousness of the menace in the British Isles has not yet been realised.

The Background of International Relations: Our World Horizons, National and International. By Prof. C. Hodges. Pp. xvi + 743. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 21*s*. net.

AN excellent compendium of world politics viewed from a common-sense angle, this book illustrates the point that international politics should be everybody's business. The basic principles of politics are the refined result of the crowding of the globe and the struggle for elbow-room and racial survival. So business has become the driving force in politics; and economic hunger drives nations to seek commercial supremacy backed by the power of the State. Yet enlightened self-interest forces these nations into world co-operation through political or non-political means. Yesterday's isolation of nations has gone: statesmanship has now to deal with news-minded nations. The author believes that knowledge alone can control the destiny of peoples, and that world-forces do not yield to emotions. There is much to be said for his final statement that peace is a state of mind, and not a political institution. A wealth of references and a good index are features which add to the practical value of this work.

T. G.

The Official Year-Book of the Scientific and Learned Societies of Great Britain and Ireland: with a Record of Publications issued during Session 1931–1932. Compiled from Official Sources. Forty-ninth Annual Issue. Pp. vii + 167. (London: Charles Griffin and Co., Ltd., 1932.) 10*s*. net.

THIS annual, which has now reached its forty-ninth year, supplies valuable information concerning learned societies of Great Britain and Ireland, including officers, conditions of membership, meetings, publications, etc., and also gives particulars of various government scientific institutions. The new form of the publication initiated last year, which involved omitting lists of papers read before societies, has been continued this year. Many societies have been added, thus adding to the value of the volume as a work of reference.

Volcanic Craters in the Libyan Desert

By Dr. K. S. Sandford

IN the last few weeks, reports of the occurrence of volcanic craters in the Libyan desert have appeared in the daily Press. It seems wise, therefore, to define the discoveries more precisely as soon as possible, although detailed study of the material collected must be postponed for several weeks.

In the spring of 1932, the late Sir Robert Clayton East Clayton and Squadron-Leader Penderel, R.A.F., observed and photographed some crater-like hills between the Gilf Kebir and Gebel 'Uweinat, near the southern end of the Egyptian-Cyrenaican frontier. Sir Robert also flew over them with Mr. P. A. Clayton, of the Desert Survey of Egypt, who, with Count De Almàsy, was a member of the expedition. Some of their photographs appeared afterwards in the *Illustrated London News*, and Mr. Clayton has sent a paper on the western side of the Gilf Kebir to the *Geographical Journal*. The party was unable to visit the craters but their approximate position was computed.

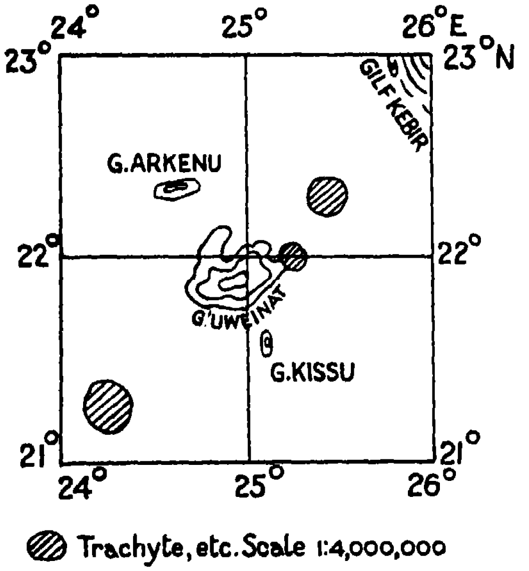

FIG. 1.

In the first week of October 1932, Capt. Craig, R.E., W. B. K. Shaw, G. L. Prendergast and I set out in a car from Gebel Kissu, the advanced base of the recent expedition led by Major R. A. Bagnold, and found the craters on the same day. Those previously seen from the air proved to be explosion craters; others, less obvious, were found to be the denuded stumps of volcanoes: both types were encircled by high ramparts of steeply tilted, hardened, and locally fused Nubian sandstone. Seven principal hills, standing 100–300 ft. above the plain, are grouped within a radius of about five miles, and to these must be added minor elevations and a thick horizontal sheet of 'lava' which caps a prominent hill nearby; this may have been a surface flow or a sill.

One of the best preserved of the explosion craters was about half a mile wide from east to west and about a quarter of a mile wide from north to south (inside measurements), with vertical walls of hardened Nubian sandstone rising 100–130 ft. above the plain. The centre, partly filled with sand and rubble, was at about the same level as the plain, and water flowing from it has cut a deep channel through the southern wall. Some of the craters evidently now contain lakes after the rare rains, and the remains of mountain sheep and other animals that came to them were common.

Within the main ramparts of at least two of the explosion craters were found subsidiary plugs of white trachytic rock, and adjacent to them the fusion of the sandstone walls was very marked. The relative ages of explosion and flow of molten rock in these multiple craters seemed to vary. Into the white rock had been intruded a dark basalt-like rock of much the same specific gravity as the trachyte: although both rocks varied appreciably in texture over the area, their mutual relation seemed to remain the same.

A noticeable feature of the whole neighbourhood was the presence of double walls of hardened sandstone, running on straight or curved courses over the surrounding plain and across some of the craters. These, and pipe-like tubes of irony sinter penetrating the unbroken Nubian sandstone of the plain, seem to have been formed by hot solutions at a late stage of the period of activity. In some, amorphous and gypseous substances occupied the space (usually four to six feet) between the parallel faces of the double walls.

During our reconnaissance from the craters to Gebel 'Uweinat, we found a similar but smaller area at the north-eastern corner of the massif. Here, in particular, prismatic sandstone, well-known to Messrs. H. J. L. Beadnell and P. A. Clayton from their surveys in adjacent areas, was intimately associated with the type of 'wall' already described.

At about this time, Squadron-Leader Penderel, who had followed our party out from the Nile valley by air, landed beside us and was kind enough to take specimens for me to Cairo, where they were given to Mr. O. H. Little, director of the Geological Survey of Egypt. I am indebted to Mr. Little for some notes which reached me on our arrival in Fasher several weeks later.

A considerable 'volcanic field' may, therefore, now be added to the map between the north-eastern corner of 'Uweinat and about lat. 22° 18′ N., long. 25° 30′ E. A similar volcanic area, with trachytic rocks, was encountered on the south-western side of 'Uweinat during the investigation of the country westward to Sarra and the Tibesti foothills. It is centred about lat. 21° 16′ N., long. 24° 14′ E., with a radius of about six miles, and most of its denuded stumps were visited by Lieut. D. R. Paterson and myself. There seem to be no explosion craters in this group.

Each 'field' is associated with very slight folds of the Nubian sandstone, and the complex of ancient rocks upon which it lies is exposed in the immediate vicinity by the denudation of the slight surviving thickness of sandstone. The period of volcanicity is obviously far younger than the Nubian series, and the fresh appearance of the explosion craters suggests a fairly recent date of formation.

The discovery of a few stone implements of Middle Palæolithic type in and near some of the craters necessitates a readjustment of ideas, which is confirmed by comparison with the great crater of Malha, in the Meidob Hills about 150 miles north-north-east of Fasher. Malha seems to have exploded but yesterday: the basaltic lavas which surround it and have flowed into one corner of it are fresher than many on the flanks of Vesuvius, yet the traditions among the people who depend on the springs within it seem to recall only variations of level of the lake in its centre. These explosion craters seem to be far older than they at first appear.

The presence of light trachytic rocks within a radius of about 50 miles from Gebel 'Uweinat is of interest in contrast to the wide distribution of basalt and dolerite over Egypt and the Sudan, ranging from an Oligocene age in Egypt to at least a semi-recent age at Malha. About 'Uweinat the dolerites seems to be of far greater age than the features described above, but there was a later effusion of basaltic magma at Malha—the presence of basaltic lava and of 'volcanoes' in the Bayuda desert between Berber and Merowe (Dongola) will be recalled—probably long after the trachytes of 'Uweinat were cold.

The Old Morphology and the New*

By DR. H. HAMSHAW THOMAS

"THE full problem of morphology is . . . to explain how in the past plants came to be such as we now see them" (Bower). The problem is often regarded as insoluble, but a survey of the development of morphological concepts suggests that some of our difficulties may be due to the tacit acceptance of theories handed down by successive generations of teachers. In dealing with the flowering plants, almost all recent writers accept the classical concepts originated by Goethe and Lindley in pre-evolutionary days. During the last thirty years, however, a large body of facts has been accumulated about the simpler and older plants, and a new system of ideas has been founded, which is in harmony with our knowledge of the form of the earliest known Devonian land plants. We have now to face the question of the relation between the fundamental concepts of the old morphology and those of the new.

At the outset of any discussion of form, it is necessary to keep in mind the principles underlying our comparisons. In the past, before the coming of evolution, comparisons of plants were mainly subjective, but to-day we aim at an objective approach. Plants are objectively comparable because we consider them to be derived from common ancestors; if we reject the subjective approach, we must introduce phylogenetic considerations.

We owe the term 'morphology' and the foundation of the classical concepts to the poet philosopher, Goethe, who published in 1790 a treatise "On the Metamorphosis of Plants", which has been called "the foundation of all that has since been done in vegetable morphology". The most important conclusion in this essay is that "whether a plant produces leaf-buds, flowers, or fruits it is still the same organ which is carrying Nature's laws into effect, though performing different offices and disguised under different forms". This one organ is called the leaf, but Goethe appeared to feel that it should be given some more generalised designation.

The spread of this doctrine in England was largely due to Lindley, who repeated Goethe's views and arguments, but he made an important modification in the theory which has received insufficient attention. Goethe wisely wrote near the close of his essay, "The thing now to be aimed at is to keep habitually in view the two contrary directions in which variations are developed. For we may say with equal truth that a stamen is a diminished petal or that a petal is an expanded stamen."

Lindley, however, concludes that "the leaf, as the first formed, the most perfect of all [the appendages] and that which is most constantly present, is properly considered the type from which all the others are derivations". This unsupported assumption was widely accepted, and Darwin in "The Origin of Species" spoke of the view that the parts of the flower consist of metamorphosed leaves as familiar to almost everyone. As the result of Darwin's work, the old concepts of the subjective and idealistic philosophers have been taken over and given an objective significance by biologists.

The doctrine of metamorphosis led to the idea that the parts of plants could be divided into three distinct categories, stems, roots and leaves. This has met with less universal approval. It may be tenable when we are dealing only with the mostly highly evolved forms, but when an attempt is made to extend it downwards grave difficulties are encountered. It has resulted in an unnatural separation of the Thallophyta and Bryophyta from the higher forms.

---

* From a paper read to the Linnean Society of London on November 10, 1932.

The major concepts of the classical views have in the course of time come to be considered as so axiomatic that few writers have troubled about the evidence on which they were based, or have followed up their implications. But modern work has cast doubt on most of the arguments used in founding the system. Grégoire has found that the primordia of the stamens and carpels at their first appearance can be distinguished from those of foliage leaves, and so is led to the view that the stamens and carpels are organs *sui generis.* The validity of arguments based on abnormal flowers was challenged some years ago by the late Prof. K. von Goebel, and more recently by Mrs. Arber on the principle of irreversibility in evolution. Thus the only uncontested evidence is that derived from comparisons during the progressive growth of the plant, which, as Goethe pointed out, may be read in two opposite ways.

It might be reasonably expected that the great outburst of morphological research which followed the rise of the doctrine of evolution would provide evidence in support of the fundamental concepts. But no fresh evidence has been obtained. The continental morphologists of the classical school reject all evidence derived from the study of comparative anatomy and vascular structure as worthless, and they likewise seem to reject considerations of ontogeny, cytology and evidence derived from fossil plants. It may be that anatomical and developmental studies are held to have no bearing on morphology because they are known to conflict with the classical concepts. Most English morphologists regard anatomical and palæobotanical work as valuable, but in attempting to apply new knowledge to old concepts find that more problems are raised than solved.

The general ideas of the new morphology which may be said to have originated twenty-four years ago with the work of Lignier, Tansley and Bower, are based on considerations of phylogeny. The forms of plants and plant organs can only be explained by reference to their origin, and even though we cannot trace back the development of a group of organisms, we may in various ways obtain glimpses of the types of change which have gone on in the past. Fragments of the evolutionary history of one group may enable us to guess what has probably gone on in another group. The classes pteridophytes, gymnosperms and angiosperms may well represent stages in evolution rather than independent groups of organisms, and there is much evidence pointing to parallel evolution in the various groups. When endeavouring to draw the broad generalisations on which a system of morphology is based, it is unnecessary to trace the complete phylogenetic history of all the groups of plants, unless we consider that the different groups have been derived from independent algal ancestors, and that all traces of the previous history of many of them have been obliterated.

Even the present incomplete state of our knowledge enables us to determine the general trend of evolution throughout the ages with some degree of probability, and it may well be that the geological record of plant life is more complete than has previously been supposed. Any general system of morphological ideas should be applicable to all plants, but only one group has yet been fully studied from the new point of view. Prof. Bower's work on the ferns provides us with evidence as to the probable evolution of this group drawn from a number of different aspects. Zimmermann, in a publication of a different character, has shown how well the new views can be applied to the gymnosperms.

From a study of the Pteridophyta and the earlier fossil plants we are led to suppose that the very early land-plants were simple structures of the *Rhynia* or *Psilophyton* type, in which there is little differentiation beyond that of the sporangia. Afterwards roots became specialised from underground branches, and in some groups small simple leaves appeared. The large leaves characteristic of most of the higher plants seem to have evolved from branch systems and long retained traces of this origin. The primitive terminal sporangia either retained their original position or became involved in frond formation and attained a marginal or superficial position ; they often formed tassel-like groups and frequently became more or less fused.

These generalisations are quite inconsistent with the classical ideas of morphological development, and call for a modification of our ideas of homologous structures. They suggest that the foliage leaves and reproductive organs of the flowering plants can only be regarded as homologous structures because they are both derived from branch systems. Stamens and carpels have never been typical leafy structures with an expanded lamina, and it is probably misleading to call them sporophylls.

These newer concepts help us to understand the gymnospermous reproductive organs. It is no longer necessary to assume that terminal ovules in *Ginkgo* and *Ephedra* were originally produced on lateral leafy organs which have disappeared without leaving the slightest trace of their former presence. There is a great gap between the Psilophytales and the flowering plants, but it is to some extent bridged by the upper Palæozoic pteridosperms. The derivation of the *Caltha* type of carpel from a *Caytonia*-like structure has already been suggested, and we can now link the Caytoniales more closely to the pteridosperms owing to the discovery in the Triassic rocks of South Africa of a new group of seed-bearing structures.

When we come to examine all the known pollen-bearing structures of the seed plants with large leaves, it seems as though we can distinguish a gradual progression along two or three distinct lines, commencing with terminal groups of separate sporangia produced in groups, and leading to Mesozoic structures which may either be like branched stamens, structures bearing bean-shaped synangia, groups of sporangia borne on the surface of a leaf-like structure, or organs resembling the male flowers of the poplar. Nothing is known of a fertile leaf like that envisaged in the classical morphology. The study of these forms, however, suggests that angiospermous flowers may have originated in more than one way.

When we examine the forms of expanded leaves throughout the past, it is impossible to avoid the conclusion that 'compound' leaves are of a more primitive type than 'simple' leaves. In certain cases, however (for example, the Date palm), a new type of compound leaf has probably arisen from a simple form.

In other branches of science the interpretation of observed facts is facilitated by making successive assumptions and by comparing the theoretical results of each with the observations already made. This procedure has not been followed in plant morphology. The old system provided one set of assumptions only, founded more than a century ago on a very imperfect knowledge of the plant world, and for many years endeavours have been made to harmonise our ever-increasing observations with these postulates, distorting or discarding all those facts which seemed inconsistent. While it is quite probable that the assumptions of the new morphology may prove to need drastic emendation, they may nevertheless serve a useful purpose in the study of plant evolution.

Obituary

MR. H. A. ROBERTS

MR. H. A. ROBERTS, secretary for thirty years of the Appointments Board of the University of Cambridge, died at Cambridge on December 18 at the age of sixty-eight years. After ten years as senior mathematical master at Bath College he returned to Cambridge as a coach in mathematics in 1898. But his life's real work began when he was appointed in 1902 to be secretary of the University Appointments Board. He was keen to develop a new line of openings for university graduates in business and administrative posts, in addition to the more obviously natural academic, professional and technical positions which most men then sought after graduation. By great care in the selection of the men whom he recommended to the firms which applied to the Board, he not only succeeded in overcoming a prejudice against university men in business but he also created a new demand for such men on the part of large industrial undertakings.

Thirty years of devoted service on Mr. Roberts's part brought their own reward in intimate and friendly relations with the heads of industry, with their younger successors who had gone into business under his auspices, and with generations of college tutors, with whom he always worked in the closest touch. Gonville and Caius College elected Mr. Roberts as a Fellow in 1927, his advice was sought in Government circles and in the formation of appointments boards at other universities and for the women's colleges at Cambridge. He retired on account of ill-health only last autumn. It is sad that he should have lived so short a time to enjoy his hard-won leisure, but it is something that he was able to attend, less than a fortnight before his death, a complimentary dinner at which a presentation was made to him on his retirement by a number of those whom he had served so well.

MR. A. R. WRIGHT

MR. A. R. WRIGHT, who died on December 24 at the age of seventy years, played an important part in organising the work of the examining staff of the Patent Office to its present high level of efficiency and was also a recognised authority on folk-lore.

Wright entered the Patent Office in 1885 and from that date until his retirement forty-two years later worked unremittingly to place the classification of patent specifications for search purposes on a sure foundation. He was the editor of the well-known official series of illustrated class abridgment volumes which were published at the rate of more than fifty volumes a year to cover, by the year 1905, all patent specifications issued up to that time from 1855. The classification scheme on which this mass of material was indexed and through which alone the official search for novelty introduced by the Patents Act of 1902 was made possible, was largely Wright's work, and its amplification in subsequent years to meet the ever-growing amount of search material in the examiners' files and the development of industries and industrial processes was carried out under his personal supervision with a thoroughness and care for detail which were characteristic of the man.

The Patent Office classification as it stands to-day, exceptional in many respects, deserves a high place among the several developed classifications of applied science, and is a worthy memorial to Wright's energy and capacity. He was appointed assistant-comptroller of the Patent Office in 1922, while still retaining the classification as his main charge, and retired from the service in 1927.

As a folklorist, Wright was known not so much for his literary output, which was not large, as for his encyclopædic knowledge of folk beliefs and customs, obtained by extensive reading and an unusually retentive memory, which was ever at the disposal of anyone seeking information, and for the valuable services he rendered through the Folk-Lore Society, of which he became a member in 1890. He was a prominent and active member of the Council of the Society from 1898 until his death, and president for the two years 1927 and 1928, while he was an invaluable editor of the Society's journal *Folk-Lore* from 1912 until 1931.

At the time of his death, Wright was engaged in editing for the Folk-Lore Society the English material which had been gathered together, mainly by his own labours, for a collection of British calendar customs which the Society had decided to publish. All folklorists will regret that his invaluable help and advice have been withdrawn at a time when they were most needed, but this should only be an added spur to see that the task to which he had given so much time and work is completed. Wright was a fellow of the Society of Antiquaries and of the Royal Anthropological Institute, and had many outside interests ranging from the collection of Utopias to the Shakespearian productions of the Old Vic Theatre, which he attended with unfailing regularity until his last illness.

MR. G. STEPHENSON

MR. GEORGE STEPHENSON, who died in Letchworth on December 29, in his seventieth year, was for many years the principal of the Albert Agricultural College, Glasnevin, and lecturer on agricultural chemistry in the Royal College of Science, Dublin. He was born in Yorkshire in 1863, and was educated for the teaching profession, but soon turned to the study of chemistry and physics in their applications to agriculture. He gained a national scholarship and went to the old Royal College of Science at South Kensington, where he studied under Sir Arthur Rücker, Sir Edward Thorpe and Sir Norman Lockyer. He was a student during the years 1887–1889, and was deeply impressed by the lectures and practical classes, and he retained his notes during his whole life. With Sir Norman Lockyer he carried out some spectrographic research, and he would show with pride the photographs he made at that time.

After leaving South Kensington Mr. Stephenson became science master at Cheadle Hulme School, and later joined the staff of the Agricultural Department of the University of Leeds, but shortly afterwards he accepted an invitation to join that of the Royal College of Science, Dublin, which had been reorganised by the Technical Department presided over by the late Sir Horace Plunkett.

A few years later whilst retaining his lectureship Mr. Stephenson was appointed principal of the Albert Agricultural College, which had been opened in the middle of the last century by the Prince Consort. Here he found the congenial work of teaching and training students, many of whom in every part of Ireland, in Great Britain and throughout the Empire have done most important and useful work for agriculture.

Mr. Stephenson, though a strict disciplinarian where order and method were concerned, was above all things a sympathetic teacher and was never so happy as when helping students, individually, when necessary, with their difficulties. Being a man of wide reading and culture his lectures often extended far beyond the usual curriculum. His students will remember him with love and gratitude, and will regret the passing of so kind and great a teacher. He leaves a number of devoted friends, who will regard his memory as one of their cherished possessions. S. S.

WE regret to announce the following deaths:

Sir John Ballinger, C.B.E., formerly librarian of the National Library of Wales, who did much work in connexion with the organisation of school and village libraries, on January 8, aged seventy-two years.

Mr. G. S. Kemp, who was the Marchese Marconi's first assistant in his first demonstrations of wireless telegraphy, on January 2, aged seventy-five years.

News and Views

British Association: New President Installed

ON January 6, the usual meetings of organising sectional committees of the British Association were held to decide the lines of the programme of the Leicester meeting next September. As under a new statute the annual office of president of the Association corresponds with the calendar year, occasion was taken to welcome Sir Frederick Gowland Hopkins to the chair. Sir Alfred Ewing, the retiring president, in introducing the new president, said that the Association has been fortunate in securing Sir Frederick Hopkins's services. Last year it had been, so to speak, the turn of that part of science which dealt with the constitution of non-living matter, and with purely mechanical processes, which can certainly kill, but cannot make alive. Now the Association turns, perhaps with relief and greater hope, to the still more difficult science of life—of the fascinating problems of which no one can speak with more authority and clearer discernment than Sir Frederick Hopkins. Sir Alfred stated that it seems not unlikely, and probably it is desirable, that in future meetings of the Association, scientific workers will make a more conscious effort to relate their studies to social problems. Science is now playing so large a part in human life, both for good and for evil, that scientific workers cannot logically stand aloof. Science has brought new powers and new dangers —grave dangers of which the community is scarcely yet aware. It is clearly the duty of science to point these out. After his installation, Sir Frederick Hopkins said that Sir Alfred can be well pleased with his tenure of office and with the delivery at York of an address which in many minds stimulated thought along desirable lines on the readjustment of science and civilisation. Sir Alfred is retiring from office in the full assurance that he has helped the Association greatly.

Miners' 'Claims' and Native Lands in Kenya

ELSEWHERE in this issue (p. 37), we have discussed the grave situation which may arise through the proposed legislation dealing with gold prospecting in native reserves in Kenya. The explanatory memorandum issued by the Chief Native Commissioner of Kenya Colony to the natives likely to be affected has now been published in the *Times* (Jan. 5). It would appear to be fundamentally opposed to the whole conception and purpose of the institution of a native reserve, and is likely to be thoroughly disturbing to the minds of natives nervous for their rights. It seems that no attempt will be made to segregate the native or to control the siting of mining claims. European interpenetration of native holdings on the reserve will be complete. The natives are informed that they may expect to see their holdings 'pegged', or such part of them as may be required, wherever it is thought worth while to look for gold, and their huts and shambas may be destroyed; while they are invited to squat on their neighbours' land and make money, pending the vacation of their own land at some indefinite date, by working in the mines. It is also suggested that natives may sell to the miner meat, chickens' eggs and vegetables, but this applies, presumably, to those who have not been dispossessed of their land. Sir Edward Grigg has rebuked the Archbishop of Canterbury for suggesting that "African interests . . . are likely to receive better and wiser consideration from 'public opinion' in this country than from the Government of the Colony"; but the anthropologist asks "*Quis custodiet ipsos custodes*"? This unfortunate memorandum, issued, be it marked, by the department responsible for the well-being of the native, passes over all that has been achieved by scientific study of native races and of the problems that arise from their unchecked contact with Europeans.

Liverpool School of Tropical Medicine

DR. J. MIDDLEMASS HUNT, who held the post of honorary dean of the Liverpool School of Tropical Medicine for many years, has, by the terms of his will, emphasised the great interest that he took in research on tropical diseases. He has made a bequest of £20,000 to the University of Liverpool in order to provide for the endowment of the chair of tropical diseases of Africa. This will greatly strengthen the position of the laboratory of the School in West Africa originally established under the will of the late Sir Alfred Jones. In the Sir Alfred Lewis Jones's bequest, a sum was set aside for the specific purpose of building a research laboratory in Sierra Leone, West Africa, but no endowment was available. The building was erected as soon as possible after the War, the first director of the laboratory and first holder of the chair of tropical diseases of Africa being Prof. D. B. Blacklock, who remained in charge from 1921 until 1929. The present director and holder of the chair is Prof. R. M. Gordon. The laboratory has a normal staff of three which, in exceptional times, has been increased to five, and combines research on West African diseases with pathological investigations of a routine nature connected with these diseases. Dr. Middlemass Hunt was impressed by the fact that this overseas development of the Liverpool School of Tropical Medicine lacks any endowment and his generous bequest is evidence of his desire to initiate the consolidation and extension of the work of this important branch of the School.

Institute of British Geographers

THE work, extending over the past two years, of various preliminary committees was brought to a conclusion on January 3 when the Institute of British Geographers held its first meeting and elected a council and officers. The initial membership is open to all present members of the staffs of university departments of geography in Britain; in the future, membership will be by election. With one possible exception, all universities, as well as a large number of colleges of university rank, in Great Britain have now departments of geography and there is thus an obvious need for co-ordinating the teaching and research work of their staffs and for permitting an exchange of views on matters of particular interest in the furtherance of the subject in the universities. The Institute is thus in no way a rival to existing bodies. In discussing problems of special interest to themselves, it is clearly not the desire of university geographers to lose the contact which they have with administrators, travellers and surveyors, amongst others, who provide so much of their material, through the Royal Geographical Society; or with the teachers who have charge of the school training of the rising generation, through the Geographical Association. At the first meeting, papers were read, on "Soils", by Mr. A. Stevens (Glasgow), on the geography of the Arab Empire in Europe, by Mr. W. G. East (London), and on a comparison between the iron industries of Northamptonshire and Lorraine, by Mr. S. H. Beaver (London). The council and officers elected are: *President:* Prof. C. B. Fawcett (University College, London); *Hon. Secretary and Treasurer:* Mr. A. A. Miller (Reading); *Hon. Assistant Secretary:* Dr. H. A. Matthews (Birkbeck College, London); *Council:* Mr. J. N. L. Baker (Oxford); Dr. R. O. Buchanan (University College, London); Prof. H. J. Fleure (Manchester); Prof. Ll. Rodwell Jones (London School of Economics); Prof. P. M. Roxby (Liverpool) and Dr. S. W. Wooldridge (King's College, London).

Centenary of Friedrich Koenig, 1774-1833

FEW things have assisted the spread of knowledge more than the invention of printing from moveable types, the mass production of paper and the introduction of the power-driven printing machine, the last of which we owe to the German printer Friedrich Koenig, whose centenary occurs on January 17. He was born at Eisleben on April 17, 1774, and, after attending school, was apprenticed to a printer of Leipzig and then worked as a journeyman. His first improvements were made in connexion with the ordinary hand press. To further his projects he came to England in 1806, and it was soon after this that he met his countryman, Andreas Friedrich Bauer (1783–1860), who possessed the mechanical skill Koenig lacked. Four patents were taken out between 1810 and 1814 and from these came the power-driven flat bed printing machine in which the paper was pressed against the type by a cylindrical roller. Through John Walter (1776–1847), two of Koenig's machines were installed for printing the *Times*, and with the appearance of the issue of November 28, 1814, a new era in newspaper production began. Koenig's success, however, was but the prelude to a long struggle against difficulties. Returning to Germany with Bauer in 1817, he founded a works for the building of printing machines at Oberzell near Würzburg, only to find it next to impossible to obtain properly skilled artisans. Five years indeed passed before the partners completed their first German printing machine, and throughout his life Koenig met with little but adversity. He died at Oberzell at the age of fifty-eight years. The business was carried on by Bauer and relations, and afterwards gained a wide reputation. The speed of an early Koenig machine was about two thousand sheets an hour. Improvements by Cowper and Applegarth raised the speed to 5,000–10,000 sheets an hour, the Hoes of America then built machines doubling the capacity and to-day the rate of printing is some fifty times as fast as that in 1814.

Royal Academy Winter Exhibition

OF the Winter Exhibition of the Royal Academy, illustrating the works of members who have recently died, one of the oldest academicians remarked that in no country could be brought together such a fine collection of sound painting from the work of men recently with us. Apart from merit, there is also the pleasure of seeing again pictures notable in their day, some of enduring appeal, while others markedly exhibit the fashion of another age. Both as regards number and interest, Orpen's pictures should be mentioned first. From the student-study, the "Hamlet Play Scene", with its dull browns and reds, the transition can be traced to the clear coldness of the colours in his recent portraits, well on the way to be 'old masters'. One of the most striking, that of the late Sir William McCormick (No. 87), will delight many readers of NATURE. Mid-Victorian days are recalled by the work of the late president, when the fashion was for stained glass windows, flowing garments and red-gold hair. Time was when in every annual exhibition one or more of Harry Tuke's pictures of bathing boys appeared. Here we have a collection of them and find them still pleasing, while Wyllie's sea-pictures are full of life and colour. In contrast with these the Lambert pictures seem wanting in atmosphere, but that of the Red Girl (No. 251) and Round Mirror (No. 260) should be noticed.

PERHAPS too low in tone for modern taste are the pictures of La Thangue, in which French influence is prominent. Great variety is shown in the works of Greiffenhagen, some of it almost heraldic, but including several character studies (Nos. 304, 306 and 325). Of contrast between an earlier and a later style there is none more violent than is exhibited in the work of Sims, from a delicate and poetic touch portraying in delicate mother-of-pearl tints the "Light that never was on Sea or Land", to strange conceptions in harsh reds, yellows and blacks. Many examples of the well-known work of Ricketts as a book-designer will be found in a case in Room IX, while his paintings are hung in the same room against a rose background. Great restraint is shown in the water-colours of David Muirhead, but more freedom is exhibited in his oil-paintings (543, 547).

Education for Industrial Management

OVER the signatures of Lord Rutherford, Sir William Bragg, Sir Josiah Stamp, Lord Eustace Percy, Lord Amulree, Sir Herbert Austin, Prof. C. E. Inglis, Sir Francis Goodenough and others, an important manifesto on "The Management Factor in Industry" was issued on December 31. The manifesto was drafted by a small committee all the members of which are voluntary workers in one or more societies or institutions dealing with functional phases of management. Of this committee, Mr. E. S. Byng was chairman and Mr. S. Townsend, honorary secretary. The manifesto emphasises the urgent need for a full appreciation of the national importance of the management function and of the rapid diffusion of management knowledge, and directs particular attention to the quality of industrial management. Systematic education for management is asserted to be one of the chief steps required to assure Britain's industrial future, and neglect of this factor is frequently responsible for our managers' failure to interpret the progress of science in terms of their own undertakings. The manifesto directs attention to the development of a science of management and points out that to an increasing degree men of high personal character and cultured vision are finding in management a sphere of high social service. They are using the resources and methods of science to raise the effectiveness of their contribution to the organisation and direction of industry.

WHILE on this side the application of scientific methods to the functions and processes of business organisation promotes greater efficiency, establishes standards, and replaces haphazard effort by the deliberate pursuit of predetermined objectives, management is also an art involving co-operation and understanding of the human factor, so that acceptance of the scientific principles and loyal co-operation in the plans of the organisation may be secured from all its members. Skill in technique; knowledge of workshop practice; sympathy with the human factor; a receptive mind and an international outlook—these elements combine to produce a type of management which represents both in purpose and in method a second industrial revolution. Attention is directed to the assistance which statistical science can give in the higher control of industry, whether in budgetary matters, departmental co-operation and responsibility, planning of sales and production or costing methods, and it is pointed out that such developments incidentally justify the increased application of technical research in industry. The manifesto concludes with emphasising the need for consolidation in the management field. Asserting that nothing short of a revolution in the general attitude to the operation of industry is needed, it appeals for serious co-ordination of efforts in this field both in the study of management science and in the exposition of its results, so as to raise the standard of management everywhere in industry.

The Case for Alcohol

IN a monograph entitled "In Chase of Truth of Alcohol", issued by the True Temperance Scientific Committee (Donington House, Norfolk Street, London, W.C.2. 1*s*.), Prof. H. E. Armstrong gives a vigorous popular exposition, couched largely in parabolic and allusive language, of the origin, relationships and uses of alcohol. In the dedication he states his conviction that in our attitude towards alcohol "we should abolish Pecksniff as our leader and become sensible, like foreign nations". He points out that while vineyards are going out of cultivation and the mash tun is shrinking, the cider-press is advancing in favour : the apple is becoming the rival of John Barleycorn. Taking a broad view of the position, alcohol and opiates (narcotics) have been alternatives throughout history : at the present day "the drunkard no longer disfigures society, but the nuisance of tobacco is everywhere and inescapable". Prof. Armstrong pictures tobacco as a powerful depressant, both of eyesight and of intelligence. Further, while the excessive indulgence in tobacco has induced in this generation a loss of appreciation of good cooking, alcohol has the opposite effect.

THE problems of nutrition and alcohol are inseparable, states Prof. Armstrong. The case against the reasonable use of alcohol as a beverage rests largely upon unsound experiments ; when taken in moderation at meals, alcohol exerts a favourable effect upon digestion. Constant indulgence in large quantities of dilute alcohol leads to obesity, owing to the effect upon fat metabolism of the lower concentration within the cells, determined by the influx of alcohol. Since the Oriental dietary is near the margin of safety, the artificial ingestion of water induced by the use of alcohol would probably favour downgrade changes and so inhibit the repair of tissues. The proportion of alcohol oxidised in the body is small, but it has a definite metabolic fuel value. As a source of mechanical energy, alcohol is a serious rival to petrol. "To the chemist, alcohol is no mere drug . . . it is a wondrous material, a true elixir of life ; the abuse lavished upon it is rarely otherwise than the abuse of ignorance. The fault lies with those who misuse it—these must be set aside, not alcohol."

Early Publication in Anthropology

Two notes, pregnant with suggestion for the field archæologist engaged in palæolithic research, appear among the communications presented to the Institut français d'Anthropologie last session (*L'Anthropologie*, T. 42, Nos. 5–6, pp. 679–682). As they indicated lines of search in connexion with matters which, it is suggested, may hitherto have escaped the attention of excavators, it was important that their publication, in however brief a form, should have been as speedy as possible. In one note, the Abbé Breuil described a spear-point of bone of Mousterian age from the cave of Castillo (Santander). No object in bone of this type of Mousterian age was previously known, except an example found by Dr. H. Martin at La Quina in 1913. M. Breuil suggested a resemblance to the wooden spear found by Mr. Hazzledine Warren, associated with a Clactonian industry, at Clacton-on-Sea, and pointed out that such finds as this indicated that the Mousterians were in fact acquainted with the working and polishing of bone. This note was followed by a second, by Dr. Martin, in which he described the bone point of Mousterian age found at La Quina and also a point, or rather poignard, made from the canon bone of a horse, which had been found in 1905. Before the discovery of this latter, bone work by the Mousterians was not known. He suggested that the rarity of Mousterian bone work was due to the fact that the deposits, in which Mousterian remains were found, were not favourable to the preservation of objects of bone, or these were not recognised by excavators. In view of the importance of these announcements, it is most unfortunate that although they were presented to the Institut at a meeting held in February last year, the report has only just been published.

International Geological Congress

THE postponed sixteenth session of the International Geological Congress will be held in Washington this year on July 22–29. A long series of excursions has been organised for the period July 9–August 30, and it has fortunately been possible, through the generous assistance of the Geological Society of America, to offer the longer excursions at a considerable reduction below the actual cost. In selecting participants, where the number is to be limited, preference will be given to geologists whose special interests accord with the major objects of the excursion, and to geologists from foreign countries. Two important changes in the arrangements should be noted. The period covered by the excursions and the general sessions now falls entirely within the summer vacation of British and European universities. The resource topic originally chosen, "Petroleum Resources of the World", has now been dropped in favour of copper resources, and authoritative papers bearing on this subject are invited with the view of the publication of a special volume. Full particulars of the conditions of membership, topics for discussion, and itineraries and costs of excursions are given in the third circular, which can be obtained, together with application forms for membership, from the General Secretary, Sixteenth International Geological Congress, United States Geological Survey, Washington, D.C.

International Congress of Physical Chemistry

ON the occasion of its twenty-fifth anniversary, the French Society of Physical Chemistry is arranging an International Congress of Physical Chemistry to meet in Paris in the third week of October of this year. Foreign scientific societies have been invited to collaborate. In addition to the usual receptions, banquets, etc., a series of discussions are being organised, dealing with outstanding physico-chemical problems, such as electronic conduction in metals and its relation to electrochemical phenomena. Communications upon this and other questions have been invited from eminent men of science in France and in foreign countries. These will be discussed at the forthcoming conference and will be published afterwards by the Société de Chimie Physique. Further information concerning the Congress may be obtained from Dr. Ch. Marie, 9 rue de Bagneux, Paris, 9e.

Mercury Arc Rectifiers

IN the *Brown Boveri Review* for October a very impressive list is given of the mercury arc rectifiers for power transmission which the firm has shipped to overseas countries. We are glad therefore to learn that these important devices for converting alternating into direct current are now being made in Great Britain by several manufacturers. For shipping abroad it is necessary that apparatus be provided with spare parts. For rectifiers these spare parts are made of porcelain, iron and steel. They cost little and can easily be kept in good condition. Two alternating current stations can be connected by a direct current link connected through two rectifiers. One rectifier converts A.C. to D.C. and the other converts D.C. to A.C. This arrangement is economical when the voltage at which power is interchanged through the link is high. This has led to the development of high-tension rectifiers. Pressures up to 50,000 volts have already been attained. Vacuum rectifiers are independent of the frequency. Mercury arc rectifiers do not operate at frequencies higher than about three thousand but from the practical point of view this matters little. It is probable that rectifiers may be used in the future for converting A.C. into D.C. for transmission along overhead wires, as difficulties arise in transmitting A.C. along these wires at full loads. If long-distance electrification of railways is ever adopted in Great Britain they would be most useful, for whatever systems are adopted by various companies, power on any other system can be transmitted to them and converted.

Meteorology in Southern Rhodesia

THE most recent Meteorological Report of the Department of Agriculture of Southern Rhodesia covers the year ending June 30, 1931. Included with it as an appendix is the Hydrographic Report for the years ending September 30, 1928, 1929, 1930 and 1931—a summary of rainfall and run-off for certain catchment areas in Southern Rhodesia, occupying four pages. The Meteorological Report contains the usual general review of the year, particulars of the climatological stations—which are all in the charge of voluntary observers or observers attached to departments other than the Department of Agriculture—and numerous climatic tables, together with a few miscellaneous items, including a tentative essay in the preparation of seasonal forecasts of rainfall based on a number of factors, such as barometric pressure at Rio de Janeiro.

THE results obtained so far indicate a degree of success that would, if maintained, be of great economic importance in agriculture, but unless the correlation coefficient of $+0\cdot77$ proves to have been an under-estimation of the degree of dependence of Rhodesian rainfall on the various factors from which it is being calculated, such successes will occasionally in future years be replaced by failures or partial failures. These should not, however, be frequent enough to make the forecasts useless to those with an intelligent appreciation of the proportion of success to be expected from given values of the correlation coefficient. Southern Rhodesia is one of those regions where the success of farming operations is very dependent upon a monsoonal rainfall that may seem ideal when the average only is considered, but which is capricious as regards its occurrence in individual years, and is too apt to occur in torrential downpours that result in an excessive loss to the soil through run-off at the surface. When farmers must face the lean years of deficient rainfall at a time of agricultural depression, it is not surprising that many fail and abandon their farms. This is mentioned in the Report as one of the factors contributing to a net loss of 32 observing stations in the eighteen months ending December 31, 1931.

Marine Biology in Ceylon

DR. JOSEPH PEARSON, in his Administrative Report of the Marine Biologist for the Year 1931 (Part IV: Education Science and Art (G). Colombo: Government Record Office, 1932), states that the year's inspection of the Ceylon pearl banks has not brought to light any new spat falls and as there are no mature oysters in large quantities at present, there is no prospect of a pearl fishery for at least another four years. The dredgings in the Gulf of Mannar, however, showed small patches of young oysters on practically all the paars, which is a promising sign for repopulation of the banks, as the heavy spat falls of 1921–24 followed a similar scattering of young oysters in 1920. During the diver's inspection of the pearl banks, in one or two places dense masses of *Avicula* spat were found attached to the *Sargassum* weed. This is known as 'false spat' and used often to be taken for the spat of the pearl oyster. The report also contains notes on the window-pane oyster fishery, chank fisheries and local fishing industries. Plans for development are sketched out and it is hoped that a fishing vessel of a modern type will soon be available by the aid of which it is proposed to carry out detailed investigations and research necessary to determine the best methods to be adopted for the bettering of the fishing industry by the introduction of modern fishing craft and modern fishing appliances.

Clothes and House Moths

A USEFUL pamphlet entitled "Clothes Moths and House Moths", by Major E. E. Austen assisted by Mr. A. W. McKenny Hughes, has recently been published by the British Museum (Natural History) as No. 14 in the Economic Series. The need for an authoritative publication, dealing with wide-spread pests of this kind, has been felt for a long time and the present pamphlet provides essential information as to the insects themselves and the best methods of dealing with them. Simple preventive measures are discussed as well as remedial treatments of a more drastic character. The pamphlet is well illustrated and includes the most up-to-date information available, free use being made of the valuable work carried out on these insects in recent years in both Germany and the United States. Applications for the pamphlet (price *6d.*) made to the British Museum (Natural History), Cromwell Road, London, S.W.7, should be accompanied by a remittance, including postage (*1d.*).

Flood-lighting and Bird-life

SINCE late in the autumn of 1931 the great marble shaft of the Washington Monument in Washington has been flooded with strong light after dark, but it was only during the autumn just past that small birds began to be found dead at its base in the mornings (Science Service, Washington, D.C.). Several hundreds were picked up in a short time during the period of the southward migration, some merely stunned but others killed outright or so injured that they died. Flood-lighting on land gives rise to the same problem as lighthouses at sea, the birds in both cases being either attracted to the light or dazzled by the light so that they strike blindly against the structure. It seems unlikely that the destruction of the birds will result in the withdrawal of the flood-lights, for not only do they add to the beauty of the Monument, but they also serve as a guide and a warning to aeroplanes, which in approaching the commercial air-port just across the Potomac River were incommoded by the proximity of a pinnacle 555 ft. high.

Radium in Canada

In 1930 radium-bearing deposits of pitchblende rich in silver, were discovered at Labine Point in the Great Bear Lake area of the North West Territories of Canada. Since then, active prospecting has been carried on. The November issue of the *Canadian Mining Journal* contains an article by Mr. H. S. Spencer (of the Mines Branch), on the assays of samples of these ores. The analyses disclose two types of ore: (1) a pitchblende-quartz and (2) a pitchblende-carbonate mineralisation containing barytes and often rich in silver. Uranium-oxide contents ranged up to 60 per cent with averages of 43 per cent on bulk shipments. In view of the high cost of radium, the importance of these discoveries needs no emphasis. (See also NATURE, Dec. 17, p. 924.)

Announcements

THE Ostwald memorial lecture of the Chemical Society will be delivered by Prof. F. G. Donnan in the Chemistry Lecture Theatre at the University of Liverpool on January 27 at 6 P.M.

THE following appointment has been made by the Secretary of State for the Colonies to the Colonial Agricultural Service: Mr. G. C. Stevenson, to be assistant botanist, Central Cane-breeding Station, Barbados.

THE twenty-fourth Kelvin lecture of the Institution of Electrical Engineers will be delivered by Sir Frank Smith, secretary of the Department of Scientific and Industrial Research, on April 27 at 6 P.M. The title of the lecture will be: "The Travel of Wireless Waves".

IT is announced in *Science* of December 23 that in view of the death of Prof. Louis W. Austin in July, 1932, Prof. A. E. Kennelly has been elected to the presidency of the International Scientific Radio Union (Union Radio Scientifique Internationale) to succeed the late General Gustave A. Ferrié.

A COURSE of lectures on some aspects and problems of medical and industrial psychology will be given at the London School of Hygiene and Tropical Medicine on Mondays and Wednesdays during the present term. The lecturers will be Prof. M. Culpin, Mr. Eric Farmer, Prof. M. Greenwood, and Dr. May Smith. The first lecture, a historical introduction, will be given by Prof. Greenwood on January 16 at 2 P.M. The course is primarily intended for students taking the diploma in public health or the diploma in industrial psychology of the University of London.

M. ALBERT PORTEVIN, president of the Society of Civil Engineers of France, will give the next annual May Lecture of the Institute of Metals. M. Portevin has chosen as the title of his discourse, "Quenching and Tempering Phenomena in Alloys". The lecture will be delivered on May 10 at the Institution of Mechanical Engineers, Storey's Gate, Westminster, commencing at 8 p.m. Visitors are invited. Cards of admission are obtainable from the Secretary of the Institute of Metals. The Institute, which this year celebrates the twenty-fifth anniversary of its foundation, will hold its annual general meeting in London on March 8–9.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A part-time lecturer in botany at the Chiswick Polytechnic, Bath Road, Bedford Park, W.4—The Principal (Jan. 18). A lecturer in organic chemistry at Auckland University College, New Zealand—The Secretary of the Universities Bureau of the British Empire, 88A, Gower Street, London, W.C.1 (Jan. 28). A professor of electrical engineering at the Heriot-Watt College, Edinburgh—The Principal (March 24).

Letters to the Editor

Gonad-Stimulating Hormones in Hypophysectomised Animals

EXPERIMENTS previously reported[1, 2, 5, 6] on the effect of gonad-stimulating hormones in hypophysectomised animals have yielded somewhat contradictory results, probably because the number of animals studied has never been large. One of us (H. S.) has recently hypophysectomised more than six hundred albino rats by a modification of the Smith technique, by means of which it has been possible to complete the operation within five minutes, with unusually low immediate mortality, and we wish to present here a preliminary report of our findings.

The testes of hypophysectomised male rats, whether immature or adult, undergo atrophy, with reduction both of germinal epithelium and of interstitial tissue; the epididymides, prostates, and seminal vesicles are also much reduced in size. Treatment with the anterior pituitary-like hormone of the human placenta ("A. P. L.")[3] does not prevent degeneration of the germinal epithelium, but the interstitial tissue displays marked over-development, and there is consequently no atrophy of the accessory sex organs.

Noguchi[4] says that, in the ovary of immature hypophysectomised rats under the influence of pregnancy urine or placental emulsions, the thecal cells proliferate, becoming in appearance like lutein cells, although no true corpora lutea are formed. He further states that in such cases sometimes continuous œstrus sets in. Evans[5], however, thinks that a pregnancy urine fraction (prolan) cannot work at all in the absence of the pituitary, and bases on this his theory of prolan action. It seems to us that our own extensive experimental material proves beyond doubt that A. P. L. does act on the ovary of the hypophysectomised rat, though this action is not the same as in the normal. Immature hypophysectomised females treated with A. P. L. fail to come into œstrus, whereas hypophysectomised adult females similarly treated show continuous œstrus (vaginal cornification) for days and even weeks. Immature females which have been injected for five days or more with A. P. L., in order to induce precocious puberty, and have then been hypophysectomised, also respond to continued A. P. L. treatment with continuous œstrus. It is clear that the response of the hypophysectomised female to A. P. L. is conditioned by the state of the ovary at the time of operation.

We have confirmed the finding of others that hypophysectomy leads to atrophy of the thyroid, adrenal cortex, and gonads, and to cessation of growth (which last, however, does not occur immediately in rats weighing less than 50 gm. at the time of operation); these processes are not checked by the administration of A. P. L. Nevertheless, A. P. L. does cause the appearance of pseudocorpora lutea in the ovaries of females hypophysectomised before puberty, and it evidently evokes a secretion of œstrin from the shrinking ovary of the adult hypophysectomised female, since ovariectomised hypophysectomised animals did not manifest an œstrus response.

We have also found that hypophysectomy of adult females, either immediately after parturition or later in lactation, leads very rapidly to retrogression of the mammary glands and failure of milk secretion; although maternal instinct is not impaired and the young still attempt to suckle until they perish. Neither control operations upon the sella turcica without removal of the hypophysis, nor ovariectomy, will lead to this failure of lactation.

We have also been able to confirm Smith's[1] finding that hypophyseal implants permit apparently complete replacement therapy; with alkaline extract of bovine hypophyses, we have obtained growth of hypophysectomised animals without checking the atrophy of the thyroid, adrenal cortex, and gonads.

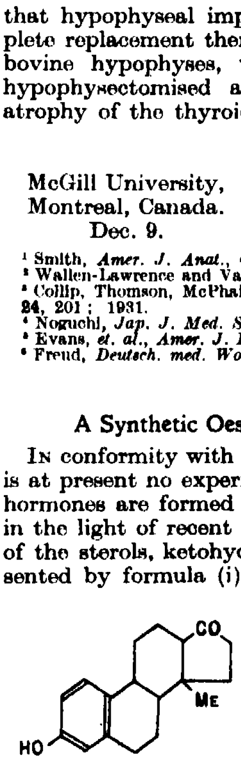
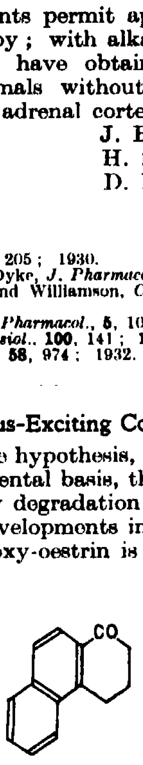
A Synthetic Oestrus-Exciting Compound

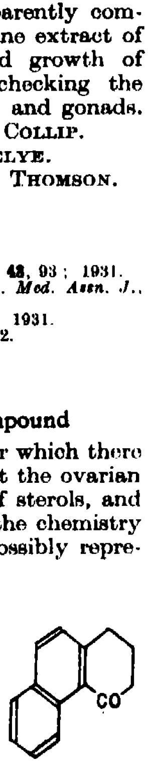
IN conformity with the hypothesis, for which there is at present no experimental basis, that the ovarian hormones are formed by degradation of sterols, and in the light of recent developments in the chemistry of the sterols, ketohydroxy-oestrin is possibly represented by formula (i).



(I)



(II)



(III)

This accords with all the facts supplied by the work of Butenandt[1], Marrian[2], and others, and we decided that the arguments in favour of this formula were sufficient to justify attempts to synthesise compounds of this nature. By analogy with other physiologically active compounds, it seems likely that a whole group of substances of related chemical constitution will be found to have oestrus-exciting properties, and the synthetic production of such substances would probably be of considerable clinical value.

We have found that 1-keto-1:2:3:4-tetrahydrophenanthrene (ii), which we propose to utilise as a starting point in the synthesis of a substance of formula (i), has itself very definite oestrogenic action, although the dose required is very large in comparison with oestrin. The oestrus-producing activity of the substance was examined by the Allen and Doisy procedure. The technique followed was that described by Allan, Dickens and Dodds[3]. The material was dissolved first in olive oil, and later in sesame oil. It was found that the substances were not readily soluble in olive oil, with the result that large volumes had to be administered subcutaneously to the ovariectomised animals. This proved to be unsatisfactory owing to leakage from the site of injection and intolerance to the oil, but with sesame oil the volume could be kept down to 2 c.c., and these adverse effects avoided. 25 mgm. of the substance in olive oil administered to ten ovariectomised rats produced no sign of oestrus, the animals remaining in a state of di-oestrus throughout the experiment. A batch of twenty animals injected with 50 mgm. dissolved in olive oil showed seven full oestrus responses, with three animals just short of the definition (a few leucocytes). In a series of twenty animals injected with 100 mgm. dissolved in sesame oil, a very much better response was obtained, all twenty animals going into oestrus. The oestrus in each case was complete.

In the case of the 50 mgm. dosage, oestrus appeared after 54 hours and terminated 150 hours after injection. In the case of the 100 mgm. in sesame oil, oestrus appeared after 52 hours. At the present moment, it is impossible to state the activity of the material in terms of oestrin since the relatively difficult solubility of the material together with the consequent difficulties of administration and absorption make a comparison impossible. Some form of 'cross-over' method must therefore be evolved. There can be no doubt that a repetition of the standardisation experiments with 50 mgm. dissolved in a small volume of sesame oil would indicate much greater potency than a similar experiment conducted with olive oil as the vehicle.

The observations show that 1-keto-1 : 2 : 3 : 4-tetrahydrophenanthrene is capable when injected into castrated animals of inducing oestrus of an exactly similar type to that obtained by the injection of oestrin. This result is of importance, for 1-keto-1 : 2 : 3 : 4-tetrahydrophenanthrene is the first compound of known chemical constitution found to have definite oestrus-exciting activity and furthermore, its molecular structure has many points of resemblance to the structure suggested for ketohydroxy-oestrin. There is thus provided the first step in the task of defining the molecular conditions necessary for this type of physiological activity, and there are grounds for hoping that substances of a much higher order of activity will be found before very long.

The observation[4] that oestrogenic properties of a low order are possessed by suitable extracts of such a variety of materials as peat, brown coal, lignite, coal tar and petroleum is of interest, but in view of the fact that many such materials are known to contain carcinogenic constituents, the clinical use of such extracts without very stringent refinement is scarcely to be entertained.

We have also examined 4-keto-1 : 2 : 3 : 4-tetrahydrophenanthrene (iii) and 3-hydroxyphenanthrene; these gave no oestrus response when injected in doses of 50 mgm.

We are indebted to Dr. H. Allan for kindly checking over the animal experiments.

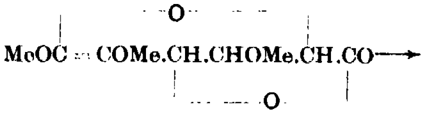
A New Unsaturated Derivative of Glucuronic Acid

COX, Hirst and Reynolds[1] in investigating Szent-Györgyi's hexuronic acid, have suggested that this acid may have the following structures:

$$\mathrm{COOH.CO.CO.CH_2.CHOH.CH_2OH} \rightleftarrows$$
$$\mathrm{COOH.CO.C(OH)=CH.CHOH.CH_2OH}$$

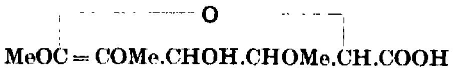
It will be noted that the second (enol) structure has a double bond. The acid reduces neutral silver nitrate, Fehling's solution, iodine and neutral permanganate[2], and yields a trimethyl ether and a triacetyl derivative.

In the course of recent work on glucuronic acid compounds of animal origin, we have methylated glucurone (the lactone of glucuronic acid) with silver oxide and methyl iodide, and obtained two crystalline methylated derivatives (see Pryde and Williams[3]), which were at first thought to be stereo-isomeric trimethyl glucurones. Further investigation has shown that only one of these compounds was trimethyl glucurone ($C_9H_{14}O_6$, m.p. 131°-132°, $[\alpha]_{5461}$ $+197 \cdot 5°$ in water). The second crystalline compound was found to decolorise rapidly permanganate and bromine water, and analysis showed it to contain two hydrogen atoms less than trimethyl glucurone. It has been called trimethyl glucuralone ($C_9H_{12}O_6$, m.p. 88°, $[\alpha]_{5461}$ $+ 110 \cdot 8°$ in water), on analogy with the glucals since we regard it as possessing a 1 : 2 unsaturated linkage[4] as follows:



$$\mathrm{MeOC{=}COMe.CH.CHOMe.CH.CO} \longrightarrow$$

Lactone



$$\mathrm{MeOC{=}COMe.CHOH.CHOMe.CH.COOH}$$

Acid

Its formation is ascribed to the mild oxidising action of silver oxide during the course of the methylation procedure, further oxidation being, no doubt, prevented by the substituent methoxyl groups. The suggested structure affords certain analogies to the enolic formula now ascribed to adrenal hexuronic acid, in that our substance would appear to be an unsaturated derivative of an aldo-uronic acid having (as the lactone) three free hydroxyl groups.

Mechanism of γ-Excitation by β-Disintegration

UP to the present, we have no system of relativistic quantum theory, and speculations about the process of emission of nuclear electrons may be permitted. In the recent work of Heisenberg, the stability of the nuclei relative to electron emission is treated on the basis of the energy balance conditions in such transformations. I propose to try to give here a detailed picture of electron emission and the excitation of the nucleus connected with it.

According to the views now generally accepted, every nucleus is built up of a number of α-particles, neutrons, and, for the elements of odd atomic number, one proton. The α-particles, possessing no spin, must be all placed on the same energy level, while on the other hand the neutrons must be distributed between the different energy levels inside the nucleus, two neutrons on each. The proton, having the same mass as a neutron, must have inside the nucleus approximately the same energy levels (differing by a constant, if we normalise to zero the potential at infinity) and in this sense may be assigned to the first neutron level.

Suppose now that for some reason one of the nuclear neutrons is unstable, and, releasing an electron, is transformed into a proton. We may suppose that it will be a neutron from one of the upper energy levels, as in this case the work of extracting an electron from the nucleus will be less. After the electron has gone, the remaining proton will find itself on the high energy level, and will fall, emitting energy in the form of hard γ-rays. If such a process takes place when the nucleus already possesses one nuclear proton, a new α-particle is formed and the γ-energy emitted will be somewhat larger.

This view explains at once why the β-disintegration is so often (in contrast to α-disintegration) accompanied by high energy γ-spectra of great intensity, and why the γ-rays emitted by odd elements are much harder than those emitted by even ones. This hypothesis on the mechanism of γ-excitation can also throw light on the results of recent experiments of Gray and Tarrant on the characteristic emission of stable nuclei under the action of hard γ-radiation. The hard γ-radiation falling on a nucleus interacts with one of the neutronial electrons (it can be shown that the action of γ-radiation on the heavy constituent part of the nucleus is very small) throwing it out from the nucleus. Just as in the case of natural β-decay, the remaining proton will fall, emitting characteristic γ-lines.

To test this theory, it will be of interest to look for the trace of emitted electrons and for the difference between the behaviours of even and odd elements. As the experiments of Gray and Tarrant deal only with the even elements (oxygen, iron, tin, lead), the investigation of an odd element, say copper, will be necessary.

Band Spectra which appear near Visible Triplet Lines of Mercury

RECENTLY, H. Kuhn[1] has found a band which appears very near the principal series lines of alkali metals in absorption and has explained this band as being due to the diatomic molecules loosely combined by Van der Waals' cohesion forces. In the case of mercury, it seems that bands of the same nature are also emitted very close to the visible triplet lines $2\,{}^3P_{0,1,2} - 2\,{}^3S_1$ which are not a principal series, in addition to the 2540 A. band beside the resonance line, and that these bands are well developed in the case of electrodeless excitation of the vapour with high-frequency oscillatory current.

In order to obtain a reliable spectrogram of such faint bands near the strong emission lines, it was, of course, necessary to take various precautions to obviate 'ghosts' and hallations of the plate. One of the microphotometric curves of the spectrogram in the near region of every visible triplet line is reproduced as Fig. 1. The upper corresponds to that obtained from the tube of the so-called reflux condensation type excited by an electric current of 10^8 cycles and the pressure of the vapour was estimated to be about 1 cm.; while the lower corresponds to that from an ordinary alternating current mercury lamp cooled with an air blast, which is used for comparison. From the upper curve, it is easily seen that the bands *a* and *b* on the red side and the band *c* on the violet side of the main lines appear well in this condition of excitation, and the long wave-length side of the bands *a* which appear beside the main lines are very sharply edged at 5467·7, 4362·6 and 4049·1 A. respectively. There are also to be observed several bands in the region between the sharp edges of the *a* band and the main lines such as the bands at 2540 A.[2] The wave-lengths of the *b* bands are measured as 4377·4 and 4053·1 A. respectively, while that of the *c* band is 4038·1 A. Other groups of bands of the same appearance are also observable in the neighbourhood of these triplet lines; whether they are connected with the lines or not is not clear. The maximum intensities are situated at 5492·7, 5483·6, 5473·5, 4364·8, 4064·1, 4060·8, 4050·4 and 4023·8 A. respectively.

Hyperfine Structure in Aluminium

FOLLOWING a suggestion of Prof. Paschen, that the hitherto unexplained doubling of several terms in Al II observed in his investigations of this spectrum[1] might be due to a nuclear moment, I undertook an examination of the structures of some aluminium arc and spark lines. The spectra were produced in a Paschen hollow cathode cooled by liquid air, following the method of Schüler. The tube was filled with helium. The lines were resolved with Fabry-Perot etalons which were silvered by evaporation for the visible spectrum and coated with Hochheim alloy for the ultra-violet spectrum. A reflection echelon was also used.

A very distinct hyperfine structure was found in the spark line λ 2669·166 $(3s^2)\ ^1S_0-(3s3p)^3P_1$, the line being double with the weaker component about 0·2 cm.$^{-1}$ to the longer wave-length side. This indicates a normal splitting of $^3P_1$ by a nuclear moment which is probably $\frac{1}{2}\,.\,h/2\pi$. Entirely in agreement is the doubling of the arc lines λλ 6696·07 and 6698·73 $(3s^2\ 4s)^2S_{1/2}-(3s^25p)^2P_{1/2,3/2}$ which are both split with a separation of about 0·04 cm.$^{-1}$ due to the ^2S term. Doubling is also clearly to be seen in the arc lines $(3s\ 3p^2)^4P_{3/2,5/2}-(3s\ 3p\ 4s)^4P_{5/2}$ at 3057·155 and 3050·073 A. classified by F. Paschen[2]. Fig. 1 shows the last mentioned lines as photographed at etalon separations of 10 mm. and 12 mm. In these lines probably both terms are split. Hyperfine structures in several other aluminium arc and spark lines have been observed, and the investigation is being continued.

Previous attempts to detect hyperfine structure in aluminium lines have been made by Gibbs and Kruger[3] and by Tolansky[4] who followed a suggestion of White[5] that Gibbs and Kruger's negative results did not constitute complete evidence against the existence of a measurable fine structure in aluminium. He did not succeed, however, in resolving any lines of Al I and III. Preliminary photographs of the arc lines λλ 3944·025 and 3961·537 found simple by the previous investigators have been taken with the reflecting echelon and seem to indicate a splitting of these lines also. From the present results, it is seen that aluminium has a nuclear moment and a not unusually small $g(i)$ factor.

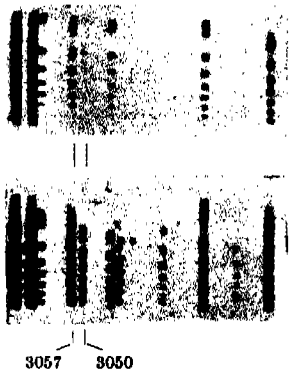

FIG. 1. Fabry-Perot patterns of the aluminium arc lines 3057A. and 3050A. Above, 10 mm. plate separation; below, 12 mm. plate separation.

Fixation of Mitochondria

DR. J. R. BAKER[1] has pointed out that, contrary to what has hitherto been accepted, mitochondria in animal tissues are not dissolved when lipide solvents and particularly acetic acid, are used in the fixative.

As regards plant tissues, Zirkle[2] states:—

(1) "Acetates do not give a basic fixation image and never preserve mitochondria."

(2) "Small traces of acetate will prevent the fixation of mitochondria regardless of the pH."

(3) "No matter how alkaline the acetate may be it never gives a basic fixation image. Always the hyaloplasm, nuclear lymph and mitochondria are destroyed. This is not only true when acetates are used alone but also when mixed with other reagents, for they penetrate so rapidly that they are the chief determiners of the fixation image."

(1) Using chromic acid 2·5 per cent, pH 1·0, he says:

"Mitochondria are nowhere preserved, though they are destroyed probably only in the outer part of the tissue, for when the fixed material is treated subsequently with $CuCr_2O_7$ (pH 4·6) some mitochondria are found in the central cylinder."

(2) Using potassium dichromate.

At pH 4·4, potassium dichromate containing no free acid gives a fixation image showing mitochondria in the outer part of the tissue, though owing to the slow penetrating power of the dichromate they are rarely fixed in the central cylinder. If the alkalinity of the dichromate be increased to pH 6·0, the fixation image shows mitochondria rather spherical in shape.

(3) Finally, according to Zirkle, the range of pH 4·2–5·2 in the use of dichromates is a "critical range". Fixation images on the acid side of this range show no mitochondria, while on the alkaline side the mitochondria seem to be quite well preserved.

I find that in a preparation of some root-tip material of *Althæa taurinensis*, which was fixed in La Cour's[3] 2 *BE* for the purpose of chromosome count, numerous mitochondria are observed, although the fixative contains acetates. The essential fixing agents in this fluid are chromic, acetic, and osmic acids, and potassium dichromate, and it has a pH of 1·8, while the fixatives used by Zirkle ranged in pH in the acetate series from 3·6 to 6·2, and in the chromate series from pH 1·0 to 6·2.

Dr. Baker suggests that the mitochondria are insoluble in acetic acid when they have a high protein content. The difference in pH between La Cour's fluid and those used by Zirkle would indicate, however, that the pH of the fixing fluid may determine whether mitochondria are soluble or not in solutions containing acetic acid.

The result which Dr. Baker obtains for animal cells would therefore appear to be equally true of plant tissues, but for a different reason from the one he suggests.

Dimensions of Fundamental Units

A GREAT simplification in electrical and magnetic dimensions which is not adopted by Prof. W. Cramp[1] or emphasised by Prof. F. M. Denton[2] is obtained by admitting that as we cannot determine experimentally the dielectric and magnetic constants of space, we have no right to introduce k_0 and μ_0 representing these hypothetical quantities into our equations and should confine ourselves to the numerical k's and μ's of material media.

The omission of k_0 and μ_0 produces startling simplicity; the C.G.S. unit charge and unit pole both become 1 dyne$^{\frac{1}{2}}$ cm., the electrostatic unit of capacity becomes 1 cm., instead of 1 k_0 cm., and so on. Incidentally, I suggest that this method of indicating the dimensions of a physical quantity by giving one of the units commonly employed in measuring it has some advantages. The velocity of light in space, as the electromagnetic constant, c, comes naturally into all the equations connecting electrical and magnetic quantities—for example, the work done in taking a pole m round a closed path linking once with a current i is $4\pi mi/c$—instead of being hidden away as $1/k_0{}^{\frac{1}{2}}\mu_0{}^{\frac{1}{2}}$.

This way of regarding electrical dimensions appears to me to be much better than the $\mu_0\, k_0$ method and it is tacitly approved by all physicists who give capacities in centimetres instead of in k_0 cm. So far, however, I have only seen it formally adopted by German physicists.

As the writers of the letters quoted above have pointed out, fractional indices may be avoided by employing a unit of electricity as one of our fundamental units and writing, for dyne$^{\frac{1}{2}}$, C.G.S. unit charge per cm.

Catalytic Hydrogenation of Olefinic Compounds

IN a recent paper[1] it has been shown that the course of catalytic hydrogenation in a series of butadiene acids $R_1R_2C{:}CR_3.CR_4{:}CR_5.CO_2H$ varies from member to member when the operation is carried out with a platinum catalyst at room temperature and atmospheric pressure. More recent work shows that the figures then recorded for the proportions of the components of the reduction mixture at the stage of 50 per cent hydrogenation are by no means to be regarded as characteristic of the respective acids, since by using an 'aged' catalyst the course of hydrogenation of sorbic acid, $CH_3.CH{:}CH.CH{:}CH.CO_2H$, follows a course which is considerably different from that previously observed. Both the original and the new observations can be readily repeated.

The condition of the catalyst thus materially affects the relative extents to which $\alpha\beta\gamma\delta$-tetrahydrogenation and $\alpha\beta$-, $\alpha\delta$- and $\gamma\delta$-dihydrogenation occur simultaneously; consequently the nature and extent of substitution in the butadiene chains is not, under the conditions employed, the sole or apparently the most important influence in determining the course of reaction. The substitutional or constitutive influence (activating or deactivating) appears to be superimposed on a specific catalytic influence which of itself can activate both unsaturated centres of the conjugated system simultaneously.

Definite conclusions were reached several years ago by Lebedev and his collaborators[2] with respect to the order of reducibility (in competition) of (*a*) mono-, di-, tri- and tetra-substituted olefinic substances and (*b*) olefinic and conjugated di-olefinic substances. These conclusions, which were based largely on the form of the hydrogen-absorption curves (rate/time) for binary mixtures of mono- and di-olefinic substances, have now been rigidly verified, so far as numerous binary mixtures of Δ^{α}-, Δ^{β}- and Δ^{γ}-hexenoic acids, Δ^{γ}-pentenoic acid, allyl alcohol and sorbic acid are concerned, by chemical analyses of partial reduction products. Thus in the hydrogenation of sorbic acid, the whole of the conjugated acid disappears before the three isomeric ethylenic acids produced in the reduction suffer attack; moreover it is easy to follow quantitatively the disappearance, which proceeds at a constant rate, of the conjugated acid and the corresponding appearance of its saturated and ethylenic derivatives.

Rate of Burning of Colloidal Propellants

IN a paper[1] recently published by F. R. W. Hunt and G. H. Hinds, use is made of physical data quoted by ourselves in a previous publication[2] dealing with the general problem of the combustion of colloidal propellants. They draw conclusions which are directly at variance with our own in the case of three out of the four propellant compositions considered, in that they deduce for the rate of burning a pressure law, as against the temperature-density law advanced by us.

In analysing the data they have adopted the hypothesis that a formula given by us[2], for assigning numerical values to the energy losses at the end of combustion, can when slightly generalised be applied to calculating the energy losses at any stage during the combustion. They have then proceeded to correct the pressure at each measured time interval, and in this way they have arrived at a hypothetical uncooled pressure-time curve (that is, the curve that would be presumed to have been obtained, had there been no energy loss at any instant during the explosion). From these values for uncooled pressure they have calculated corresponding fractions of charge burnt, and assuming no alteration in the time scale they have proceeded to apply a criterion to determine whether the rate of burning is proportional at any instant to their corrected uncooled pressure, or to their deduced gas density.

Such a procedure appears to be of doubtful validity. In the first place, the energy loss equation referred to was based on the assumption of a mean gas temperature holding throughout the burning, equivalent to that obtaining at the instant of complete combustion. This assumption was sufficient for the circumstances in which the formula was applied by us, namely, the assessment of the order of magnitude of a summation energy loss effect at the end of the explosion. A formula of this type, however, with an assumed average temperature and an appropriate fitting constant based on end conditions, cannot be used for assessing with sufficient accuracy varying temperature values during the burning for the purposes of any differential treatment, though it may yield values of approximately the right order of magnitude.

In the second place, even if for the sake of argument it be conceded that the formula may be put to such a use, the method adopted by Hunt and Hinds of calculating the value of the correction at each stage is open to objection. The main correction term depends on the value to be assigned to the fraction of charge burnt. This the authors have taken to be equal to the ratio of the observed pressure at any instant to the maximum pressure, an assumption which is unnecessary in view of the fact that they have available three equations by means of which the value of the fraction burnt, following their method, can be calculated, and the appropriate correction term deduced. Had they adopted this procedure they would have arrived at values differing from those they have actually employed.

Such difficulties always attend any attempt to deduce by differential methods the nature of the rate of burning law of propellants from experimental measurements of pressure and time only, and for this reason we have been led to investigate the possibility of ascertaining the temperature as well as the pressure at any instant during combustion. A technique for this purpose has been developed and experimental values are now being examined.

Although the analysis is not yet complete, the results so far available indicate that for the propellant compositions in question the rate of burning is in each case governed by a temperature-density law, and not by a pressure-law. We hope to be in a position shortly to publish details of our further investigations.

The Bacterial Growth Curve and the History of Species

WHEN a nutrient solution is inoculated with a species of micro-organism, in pure culture, the curve obtained by plotting the population against the time is characteristic and conforms to a general type of growth curve; an initial period of slow increase in numbers being followed by a rapid rise in population which, in turn, is superseded by a decline. An example of such a curve, representing the growth of a species of *Actinomyces* (measured by the evolution of carbon dioxide) in glucose solution,[1] is given in Fig. 1. Winslow[2] recognises five phases in bacterial growth curves: (i) phase of adjustment, *A–B*; (ii) phase of increase, *B–C*; (iii) phase of crisis, *C–D*; (iv) phase of decrease, *D–E*; (v) phase of readjustment, *E–F*: it is worthy of remark that the diminution in numbers following the period of crisis appears to be due neither to a deficiency in the food supply nor to the formation of toxic substances.

The examination of a variety of natural growth phenomena supports the view that this type of growth curve is fundamental and of universal occurrence. It may well be that the history of each living species, at all events of the terrestrial forms, is represented by such a curve when its natural evolution is undisturbed by such abnormalities as geological upheavals and the advance of civilisation.

Assuming a new species arises as a mutation in an existing species or an existing species enters a new geographical zone, it would be anticipated that considerable difficulties would be encountered before the species becomes established, and this period would correspond to Winslow's phase of adjustment. During the phase of increase, which follows if the species can survive the initial stage, there will still be a considerable degree of instability which will be expressed in individual variation, and in this connexion it is relevant to note that H. D. and E. B. Ford[3] found that, in an isolated colony of *Melitæa aurinia* kept under observation for some years, an increase in the population corresponded to a marked incidence of variation. It is during this phase of increase that a species is most likely to extend its geographical range and also to give rise to new species, for the population is approaching a maximum and contains much highly variable material. With micro-organisms, the phase of crisis, during which the population remains constant, is invariably of short duration although it does not necessarily follow that this is the case with all organisms; but it may be that this stage marks the disappearance of the tendency towards variability and the cessation of the production of new species. Nevertheless, it would seem that the major portion of the life of a species is occupied by the final phases of decrease and readjustment in which there is a gradual decline in numbers and little tendency towards variability.

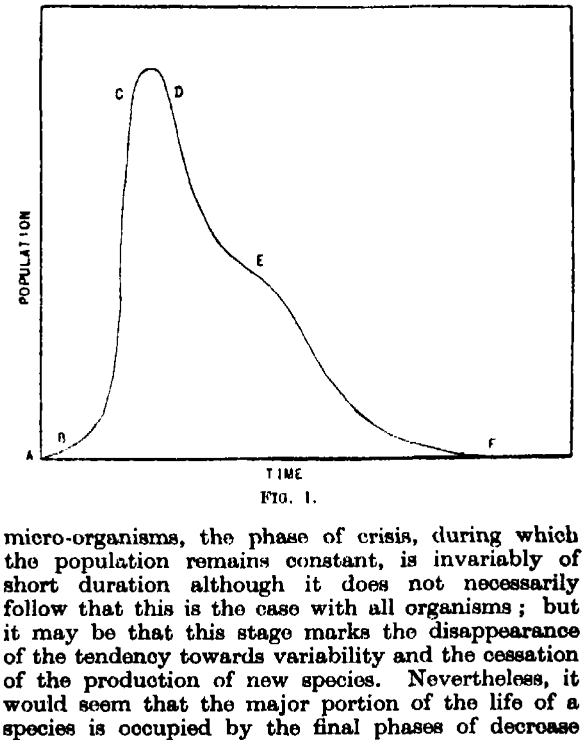

FIG. 1.

If these conclusions are correct, a comparatively young species will be characterised by (i) much individual variation; (ii) no well differentiated geographical races; (iii) a number of closely allied species in the genus. On the other hand, a species which had entered the final phases would exhibit (i) little individual variation; (ii) well differentiated geographical races; (iii) few or no similar species in the genus. It has been found that the species of Malaysian Rhopalocera in which the sex ratio is abnormally low have the characteristics associated with old species.

Close observation of certain Indo-Malaysian species of Rhopalocera over a period of five years has revealed that, so far as they can be tested, the conditions amongst these insects are compatible with the conclusions stated above, but the case of migratory species has not yet been examined and probably requires separate consideration. The Indo-Australian genera *Eurema*, *Amathusia* and *Ambly-*

podia all contain a large number of very similar species and doubt still exists as to the status of certain species in the last two genera named. *Eurema hecabe* and *Amathusia phidippus*, the two most widely distributed members of their respective genera, both exhibit marked individual variation, the geographical races are not readily separable, the sexes occur in approximately equal numbers and both so closely resemble certain allied congeneric species that determination is frequently a matter of doubt and difficulty. On the other hand, species such as *Papilio brookiana*, *Parcronia valeria* and *Ideopsis daos*, in which the females are strikingly rare, have well-defined geographical races but exhibit little or no individual variation and have no close allies. Such instances can be multiplied.

Application of the views expressed here to mimicry amongst Malaysian butterflies is of great interest. The models of the 'true' mimetic butterflies of the Malay Peninsula are members of the Aristolochia group of the genus *Papilio*, the genus *Delias* or the family Danaidæ, and the larvæ of these are known to feed on plants containing toxic substances. As a rule, the mimetic butterflies are rare but, in cases where their habits are sufficiently known, they are found to have the characteristics of old species, having no close allies, a low sex ratio and exhibiting little individual but marked subspecific variation. This state of affairs suggests that the mimetic forms have ancient wing patterns which have been preserved through the agency of natural selection owing to the advantages associated therewith.

The equable conditions of life prevailing in the tropics, which must be of considerable assistance to new species during their early struggles for existence, and the large number of broods produced annually, indicate that it is in equatorial regions that most new species have been produced.

It is hoped that, at a subsequent date, it will be possible to discuss the evidence which supports these arguments in greater detail than is permissible here.

Glycogen in Cartilage

WE were much interested in the letter from Prof. H. A. Harris in NATURE of December 31, p. 996, in which he directs attention to the presence of glycogen in hypertrophic cartilage cells and correlates this with a secretion of phosphatase by these cells.

We feel, however, that it should be made clear that phosphatase is also actively secreted by the osteoblasts[1,2]. According to Prof. Harris, "osteoblasts and highly vascularised bone contain no glycogen". These facts are not necessarily inconsistent with the suggestion that he has put forward.

Prof. Harris in his letter refers to the hypertrophic cartilage as "senescent". Although hypertrophic cartilage, being a transitory structure, may eventually become senescent (degenerative), the process of chondroblastic hypertrophy is not in itself a degenerative change but a specific differentiation. One of us (H.F.) formerly held the contrary view, but was forced to a change of opinion on finding that undifferentiated cartilage rudiments, when isolated and cultivated *in vitro* under standardised environmental conditions, only developed areas of hypertrophic cartilage if destined to do so in normal development, and only in that part of the rudiment where hypertrophy would normally have appeared[2,3]. Degeneration may occur in small-celled cartilage *in vitro*, but in such tissue we have never found any histological appearance at all suggestive of the chondroblastic hypertrophy characteristic of an ossification centre. Moreover, the secretion of phosphatase in cultures of either hypertrophic cartilage or of osteoblasts is always correlated with a healthy condition and not with regression, as indicated by the fact that in unhealthy, though surviving cultures, one of the first cellular activities to disappear is the production of phosphatase.

A Peculiar Visual Experience

IN NATURE of December 10 (p. 888) Dr. K. Mackenzie describes visual sensations consequent on the sudden subjection of his eyes to a brilliant flash. A similar experience of my own may therefore be worthy of record.

At the end of June, 1922, I was bicycling from King's Lynn to Leicester. It was a fine morning and the sun was of course behind me, when a motor-car, meeting me suddenly, unexpectedly flashed the sun from its wind-screen straight into my eyes. Shortly afterwards I seemed to see splashes of blood on the road. My sight was a bit troubled, but as the appearance was pronounced and persistent I dismounted to examine the road, and found that the red was in my eyes. Riding on I noticed that the red splashes had changed to green, which after a time died away.

I cannot estimate the duration precisely, but it was considerably longer than the ninety seconds noted by Dr. Mackenzie. The circumstances were not conducive to precise observation. The importance of the experience to me is that occasionally during the following years I have noticed brief repetitions of the appearance, generally taking the form of an irregular but defined blotch, and ending in white with a purplish border. It was apparently only the right eye that was affected, at least permanently, and about two years ago it became obviously difficult to read with it. It seemed that there was a lesion of the retina over the central area and this was confirmed by an oculist. The affection is most noticeable when rising in the morning or when looking from relative darkness into a bright light.

It is true that my eyes, especially the right one, have been subjected to fairly severe use throughout fifty years, but it is to this particular experience that I refer the damage, and I would suggest to Dr. Mackenzie that he should for the present rest his eyes as much as possible and consult an oculist without delay.

Research Items

Archæological Researches in the Argentine. At the time of his death in 1924 the late Dr. Eric Boman left in manuscript an account of his archæological investigations in La Rioja in 1914, in a series of papers which have now been edited and published by his colleagues (*Anales Mus. Nac. Hist. Nat. Bernardino Rivadavia*, Buenos Aires, vol. 35). These papers deal with excavations on several sites which produced a limited amount of skeletal material, interesting for the light it throws on the distribution of artificial deformation of the head, and a quantity of painted pottery with designs both geometric and conventionalised, as well as a number of figurines. The first paper of the series is devoted to a description of three sites or cemeteries in which were found a number of urn burials of infants. The skeletal remains were much decayed and little remained which could be submitted to osteological examination. From the teeth, however, it was possible to deduce that the range of age was from three months to about five years, or a little more; while Dr. R. Lehmann-Nitsche, to whom the skeletal fragments were submitted, was able to arrive at certain deductions as to the proportions of the long bones and the changes in course of growth as compared with Europeans. The pottery was hand-made, well-fired, and belonged in the main to two types. In form, the urns were either globular with mouth either circular or elongated, or bell-shaped. They were painted with a variety of conventional designs. Many of the pots had covers formed by inverted pots and a number, in addition to the skeletal remains, contained small pots or calabashes which probably had contained food or drink for the deceased infant. Small pebbles had been scattered over the bodies. Notwithstanding the distance between the cemeteries, the similarities point to an identity of race.

Fishes from the Tonga Archipelago. A small collection of fishes is described by Mr. Henry W. Fowler ("The Fishes Obtained by Lieut. H. C. Kellers, of the United States Naval Eclipse Expedition of 1930, at Niuafoou Island, Tonga Group, in Oceania." No. 2931. *Proc. U.S. Nat. Mus.*, vol. 81, Art. 8. 1932). This is the basis for the first report ever published on the fishes of Niuafoou Island, Tonga Archipelago. Two hundred and seventy-two specimens are represented by thirty-five species, three of which are new: *Paramyxus Kellersi* (belonging to the family Echelidæ); *Salarias Kellersi* and *Salarias niuafooensis* (belonging to the family Blenniidæ). These new forms are figured in the text, the two *Salarias* species being very handsome additions to the genus, especially the latter, which has a peculiar and characteristic pattern on the upper lips and lower surface of the head extending under the chin as dark bands. The fishes altogether belong to seventeen families and twenty-five genera most of which have one or two species, *Salarias* having seven.

Land Leeches. Prof. J. Percy Moore, who has spent a season in India in the study of land leeches, contributes observations (*Rec. Indian Mus.*, vol. 34, pt. 1, 1932) on their biology, especially in the Darjeeling district and in Sikkim. The common small grass leech (*Hæmadipsa zeylanica montevindicis*) ranges in altitude from 800 ft. to 11,200 ft.; the range of other species is much more restricted. Prof. Moore states that the accounts of several previous observers represent land leeches as far more numerous than they actually are. He examined every locality within reach where they were reported to be excessively abundant, but rarely did he find them to exceed six or eight per square foot. Only during July when the south-west monsoon was well advanced and young leeches were hatching in large numbers were 14–20 a sq. ft. counted in a few cases, and only rarely would several contiguous square feet yield so many; on many square feet none would be present. On 100 sq. ft. taken at random over an acre of good leech ground, the average was 1·8 a sq. ft. On this ground were places where leeches were present in such numbers as to give the impression of great abundance, but the largest number counted on one square foot was 13 and in places one might walk fifty paces unmolested by them. *H. sylvestris*, which is widely dispersed in the fields during the rainy season, congregates during the dry season at low places where a little water or mud may remain and generally in shade. Leeches are incapable of leaping as some observers have stated, and as the results of experiments on *H. sylvestris*, Prof. Moore concludes the land leeches not only do not swim but also have lost the effective swimming reflexes. He could find no evidence that leeches feed on plant juices.

Influence of Sodium and Potassium Ions in Yeast Growth. Buchner's results render it probable that the efficacy of yeast or lactic acid bacteria in the treatment of boils depends, not merely on the suppression of pathogenic organisms in the intestines by the vigorous growth of the added micro-organisms, but partly on the purely fermentative actions of the enzymes of the yeast or bacteria. The results of several series of experiments described by Prof. Ivo Novi in the *Rendiconti della Reale Accademia delle Scienze dell' Istituto di Bologna* (vol. 34) show that yeast itself and the enzymes it contains are affected differently by variations in the containing medium. The presence of 0·5 per cent of sodium chloride retards the development of yeast, and 3–6 per cent inhibits growth and favours autolysis. Multiplication of yeast is, however, accelerated by 0·5–2 per cent of potassium chloride, and as much as 5 per cent does not stop growth. The glycolytic power of yeast killed by heating at 100° C. is, however, activated by either sodium or potassium ions in the proportion of 1 per cent (as chloride), but if this concentration is raised to 3, 6, and 16 per cent, the effects on the glycolytic power are the opposite of those exerted on the yeast cells.

Trials of Fruit Trees. The very extensive trials of new varieties of hardy fruit trees carried out by the Ministry of Agriculture and the Royal Horticultural Society have produced a crop of extremely interesting results ("Trials of Varieties of Hardy Fruits for Commercial Purposes." *J. Roy. Hort. Soc.*, 57, pt. 2, pp. 246–286). Owners of new varieties of fruit which showed promise when exhibited at the Royal Horticultural Society's shows at Vincent Square were invited to send grafts, plants or cuttings to Wisley. They were propagated on suitable stocks and were distributed to a number of sub-testing stations embracing wide variations of soil and climate. It is now possible to form an exact estimate of the value of a new introduction for commercial use in any particular area. The trials include apples, pears, plums, cherries, currants, gooseberries, raspberries, blackberries, strawberries and nuts. Each variety is estimated for yield, suitability for market, and resistance to disease and is compared with the performance of established varieties. Canning tests have also been made. Two interesting appendixes are added to the report. One states the most desirable characters of the various fruits for different purposes, whilst the other describes some of the varieties distributed for trial.

Silkstone Coal Seam of Yorkshire. Nowadays much attention is being paid to the problem of promoting the use of British coal and it is a legitimate criticism that the coal industry in its days of prosperity made little effort to accumulate and publish reliable data about its wares. Now the industry is fortunate in having this done for it by the State in its survey of coal resources. Survey Paper No. 25 (H.M. Stationery Office. 1*s.* 6*d.*) on the Silkstone Seam of South Yorkshire discloses a fuel of such high class as to deserve the greatest publicity. The seam is generally low in ash and moisture and the harder portion is justly celebrated as a house coal. The softer portions have all the most desirable properties of a coal for carbonisation either in gas works or coke ovens. In this respect its low content of alkali chloride is advantageous in minimising the destructive action of alkali on the refractories of carbonising plant.

Plan of Hochelaga. In the Italian translation by Ramusio of Cartier's "Voyages" published in 1556, there appeared a plan of Hochelaga, the Indian settlement adjoining the site of Montreal. This plan has since been accepted with deference and reproduced as authoritative, as in Biggar's "Cartier". In a recent paper (*Trans. Roy. Soc. Canada*, Section 2, 1932), Mr. W. D. Lighthall shows that the plan is not only misleading and contrary to Iroquois custom, but is also a fiction of Ramusio's engraver and was probably never seen by Cartier himself. The plan showed a circular 'town' surrounded by a palisade of scantling and sawn planks unknown to the Indians. It showed square instead of elongated houses and a disposition within the stockade quite out of keeping with the arrangement known from Champlain's pictures of Iroquois towns. From Cartier's description of the town and its site, Mr. Lighthall has drawn a new plan and located its position on the map of modern Montreal. He gives Hochelaga an octagonal shape with a diameter of about 600 feet and places it immediately to the south of the McGill University grounds.

A Gaseous Oxidation. Ritchie and Ludlam (*Proc. Roy. Soc.*, Dec.) have studied the reaction between sulphur vapour at low constant pressure and oxygen at an initial pressure of about 4 mm. The reaction vessels were provided with independently heated inner tubes of quartz or pyrex glass. The oxygen disappeared from the reaction vessel when one of these surfaces was maintained at about 500° ; and when the sulphur dioxide was rapidly removed from the reaction vessel the reaction once initiated continued after the inner tube had been cooled. The rate of the reaction was practically independent of the oxygen pressure. The process appears to be a chain reaction which is initiated at the hot wall. Sulphur dioxide is an inhibitor which breaks the reaction chains, and the steady progress of the reaction is controlled by the removal of the sulphur dioxide. When the oxygen pressure is raised, the diffusion of sulphur dioxide is hindered and the reaction velocity does not rise. The authors give a tentative explanation in terms of sulphur dioxide inhibition of the fact that the reaction always ceases while there is still a residual pressure of oxygen.

Astronomical Topics

Frequency of the Nova Phenomenon. Lund Observatory Circular for June 1932 contains a paper on this subject by Conrad Lönnqvist. He begins by noting the fact, first announced by Dr. Lundmark in 1923, and further confirmed by later research, that the absolute magnitudes of novæ at maximum are nearly constant, the weighted mean being − 6·1 mag. The novæ in the Andromeda nebula exhibited the same phenomenon, and gave a measure of the distance of the nebula, 930,000 light-years, practically the same as Hubble's determination from the Cepheids.

Accepting this result, it is possible to deduce the distance of each nova from its apparent magnitude at maximum, and consequently to find the frequency of novæ in a given volume of space, which can be compared with the estimated number of stars in that volume. In this manner, he estimates that on the average each star undergoes a nova outburst about once in 400 million years. The general order of magnitude of this period is fairly well established, but it may need multiplication by a factor ranging from 3 to 1/3. The geological record is considered to make it evident that the sun has not experienced such an outburst in the last 1,000 million years. It is noted that the distribution of novæ along the galaxy is far from uniform, and it is conjectured that regions where dark nebulosity is present, notably Sagittarius, are more subject to such outbreaks. The distribution of novæ in the Andromeda nebula is stated, on Hubble's authority, to favour the suggestion: many of them are in the dark lanes.

Bright Lines in Stellar Spectra. The number of stars now known to possess bright hydrogen lines in their spectra is steadily increasing, and it has been suggested that some may have developed this characteristic within recent times. This fact, together with the difficulties encountered in theoretical explanations of such stars, and with the well-known variations which are frequently found, render observations of this type of spectrum of considerable importance. A useful list of *Be*-type stars has recently been published by Merrill, Humason, and Miss Burwell (*Astrophys. J.*, 76, 156) in continuation of a previous list which was published in 1925.

The number of such objects discovered at Mount Wilson Observatory is 233, of which 138 make up the later list. The method of search is to examine the $H\alpha$ line, which shows the effect most strongly. In some cases this is the only emission line present, and in all cases the intensity of emission decreases in the Balmer series towards the ultra-violet, the later members being simple absorption lines. The authors give the intensities of all the hydrogen emission lines, and of the dark ultra-violet lines, as well as a considerable amount of miscellaneous information. They find that bright $H\alpha$ and $H\beta$ lines reach their maximum intensities in stars of types $B0 - B3$; and another interesting fact which emerges is the existence of a reddening effect in some of the fainter stars which may be due to the absorption of light in space.

Annual Meeting of the Science Masters' Association

THE thirty-third annual meeting of the Science Masters' Association was held on January 3-6 at the University of Bristol. The programme consisted almost entirely of a number of lectures given by the heads of various departments of the Faculty of Science of the University. In addition, a large number of visits were arranged, including a very popular one to Clifton College, where the Science School was inspected.

In his presidential address, Prof. A. M. Tyndall, director of the Henry Herbert Wills Physical Laboratory, made a departure from the traditional form in that he gave what was virtually an experimental lecture on "Gaseous Ions". His aim was to avoid a highly specialised discourse on some physical topic in an endeavour to claim the attention of the biologists, while still maintaining the interest of the physicists by a judicial selection of experiments. For the most part, his demonstrations were performed with the most simple apparatus in order to provide material which might be easily adapted to school conditions. He illustrated the methods of production of ions by means of coloured powders and soap bubbles, the phenomena of conduction, and the variation of velocity of movement of ions with their radius. Of historical interest was the reproduction of an experiment of about 1740 due to Abbé Nollet. An electrostatic charge was conveyed by thermal ions, produced by the flames of two candles, along a piece of wood, from a Wimshurst machine to an insulated ball, which, on receiving the charge, attracted small particles of paper from the surroundings. After a group of demonstrations on high-speed ions and their ionising power, Prof. Tyndall discussed shortly current theories regarding the nature of cosmic rays. Their existence in the room, despite the lead roof, was shown by a process of magnification by a Geiger counter and a three-stage amplifier. A series of sharp notes on a loud speaker proclaimed their arrival. During a brief survey of the causes of atmospheric electricity, he performed an experiment supporting the old Simpon theory, and appropriately concluded with his "attempt at lightning" which he demonstrated last year to the "children's auditory" at the Royal Institution.

Prof. W. E. Garner, Leverhulme professor of physical chemistry in the University, lectured on the "Decomposition and Detonation of Solids". He pointed out that only in exceptional cases is the liberation of gas from the interior of a crystalline lattice possible. Such a fact is in agreement with the calculations of Kossel and Stranski, who have shown that reaction centres should occur chiefly on the edges and surfaces of a solid. Decomposition results in the formation of a new interface, and it is found that the rate of reaction is proportional to its area in irreversible processes, where there is no impedance by the products. This is illustrated in the case of lead azide and in endothermic changes generally. The reaction takes place when one ion absorbs sufficient energy to set it in vibration and so allow it to pass its energy to other ions by collision. The detonation wave is probably caused by four adjacent azide ions decomposing simultaneously. With lead styphnate and barium azide there is, in contrast, an initial induction period and decomposition occurs throughout the whole mass of the crystal. The change, which follows a simple exponential law here, is a chain reaction with infinite chain length, and whereas detonation can only occur when the decomposition is accelerated, with lead azide it may take place at any stage of the reaction.

Prof. Sutton Pippard, professor of civil engineering, deliberately chose a comprehensive title for his talk, "The Contribution of Science in the Development of Aeronautics", in order that he might depict how the progress of aviation has depended solely on the close co-operation of science and practical engineering. The combination of the worker in pure science, who has no interest in practical results but can assimilate something of the engineer's outlook, and the engineer, who can appreciate the value of theoretical considerations and experimental research and give them some tangible form, has been a most powerful and happy one. From the inception to the first flight, advanced mathematical analysis and accurate experimental work must always be in contact. While admitting such a debt to science, Prof. Pippard emphasised, however, that the development not only in the theory of structures and elasticity, but also in meteorology, archæological research and geographical survey, has resulted in no small measure from the study of aeronautics.

In his lecture on "Neuro Humoral Mechanisms", Prof. R. J. Brocklehurst, professor of physiology, showed that in several instances the results of nerve activity can be adequately explained by postulating the liberation of a chemical substance which intermediates between the nerve and the tissue which it innervates. Loewi has demonstrated the probability of acetyl choline appearing in the heart after vagal stimulation and Lewis has brought forward evidence that a vaso-dilator substance, a histamine-like compound, is produced locally at nerve endings in the cutaneous blood vessels on antidromic stimulation or as a result of local axon reflexes. It is this substance, and not the injurious agent in a mechanical manner, which stimulates the sensory nerve endings. Prof. Brocklehurst is to be congratulated on his choice of subject since it is becoming one of increasing importance, but as yet has found no place in current physiological textbooks.

"The Geology of the Bristol District" was the subject of a lecture by Prof. S. H. Reynolds, professor of geology. Besides possessing all formations with the exception of the Archæan, Ordovician, Permian or Tertiary, the district is fortunate in having two of the finest sections of carboniferous limestone (in the Avon Gorge and at Burrington Combe) to be found in Europe, or possibly the world. A special feature in the Mendips is the way modern erosion has reproduced most of the pre-Triassic topography.

So popular was the address given by Prof. M. W. Travers on "The Discovery of the Rare Gases" that many members were required to stand until further accommodation had been provided. Only three phases of the story were related—the discovery of argon and the separation and isolation of neon. Interest was enhanced by the many personal reminiscences, and by lantern slides showing the laboratories and apparatus used in the original research.

The lecture demonstration of Dr. S. H. Piper on "Laboratory Vacuum Technique" was concerned with modern developments and the methods now used, since such facts are more accessible to universities than to schools. He dealt particularly with the alloy- and metal-glass seals now available, and prophesied the general use of low vapour pressure hydrocarbon oils, as prepared by Birch, in diffusion pumps. The demonstrations were of great beauty and special mention may be made of three—the method of preparing electrostatic screens *in vacuo* by distillation of metallic silver, the renewal of alkali metal traps by passing sodium ions electrolytically through soda glass, and finally the use of magnesium as a 'getter', the distillation being effected by means of electron bombardment.

The concluding address, the subject of which had been puzzling members for some time, was given by Dr. MacGregor Skene on "Charles and Erasmus". He was referring to Erasmus Darwin and his famous grandchild, who still remains, said Dr. MacGregor Skene, the greatest and best protagonist of his evolutionary theory.

The trade exhibition of apparatus and books was held in the Physics Department. There were many examples of good workmanship, especially the epidiascopes, which were displayed to full advantage in the optical laboratories. The bakelite cases for balance weights were interesting. Of outstanding interest was the display of the cycle film by Messrs. Dance-Kaufmann. This formed the subject of a demonstration and discussion initiated by Mr. H. E. Dance. The value of such films was at once apparent in the illustration of the theory of wave motion, and of the three-phase induction motor. An advantage is that only one effect is illustrated at a time, hence the teacher never loses control due to excessive detail, as is often the case in documental films. The projectors, equally adaptable to continuous and stationary films, may be operated by hand, or, in the more expensive model, by an electric motor, and can be used in daylight. The conditions of the demonstration were, throughout, those likely to be found in the class-room. The manufacturers are desirous of producing additional films of an educational type and wish to have the co-operation of science masters in editing these.

The conference, which by general agreement had been one of the most successful of recent years, ended fittingly with a tour to Cheddar in most glorious weather. F. C. TOMPKINS.

Lectures at the Physical Society's Exhibition *

MEASUREMENT OF SURFACE TENSIONS

THE first of the evening discourses associated with the Physical Society's twenty-third annual exhibition at the Imperial College of Science and Technology was delivered on January 3 by Dr. Allan Ferguson on "Surface Tension and its Measurement". Simple illustrative experiments were appealed to in order to demonstrate the existence of a surface tension in liquid films and surfaces, and the variation of this tension with temperature and with the nature of the liquid. Conditions of instability were illustrated experimentally, and it was pointed out that a knowledge of the *quantitative* laws governing these phenomena, together with an appeal to the principle of minimum potential energy, would go far to elucidate otherwise obscure phenomena.

Of the quantitative laws, the power law connecting surface tension and temperature, and Macleod's law connecting surface tension and density, together with the law of rectilinear diameters, give formulæ which represent very closely the temperature variation of liquid and vapour density, and of free and total molecular surface energy.

Conditions of drop formation were demonstrated and the formation of aniline drops in water was shown by projection, and also by means of a slow motion cinematograph film. The impact on a solid surface of an aniline drop in water was also demonstrated cinematographically, as were some of Worthington's results for the impact of liquid drops on liquid and solid surfaces.

A brief discussion was given of the principal methods for the measurement of surface tension. Simple conditions for the production and photographic measurement of large flat bubbles were reviewed, and it was pointed out that the method can be successfully used for the measurement of interfacial tensions.

Quantitative determinations of the surface tension of benzene were made by the capillary rise method, by means of the pull on a plate, and finally, by a method which involves the use of no more than a few cubic millimetres of liquid, a knowledge of its density being unnecessary. The methods were in each instance so arranged as to be direct-reading on scales visible to the audience.

CATHODE RAY OSCILLOGRAPHY

Mr. R. A. Watson Watt's lecture on January 4 at the Physical Society's Exhibition touched on a variety of aspects of cathode ray oscillography. He referred to 'domesticated oscillograms', the electrically-recorded gramophone record and the sound-track on the 'talkie' film, as illustrating the problems and limitations of oscillography, and then proceeded to discuss the special merits of the cathode ray oscillograph. It provides a radical solution of the opposing requirements of low inertia and high photographic effect which face the designer of mechanical oscillographs, it has an exceptionally high overload capacity, and the high-voltage type is ultimately limited in speed of operation only by the errors due to the finite time of transit of the indicating electrons through the deflecting field produced by the E.M.F.'s under examination.

Mr. Watson Watt showed slides of oscillograms, one delineating wave trains of frequency 25 million per second, corresponding to a wireless wave-length of 12 metres, and another of still higher frequency phenomena in which a trace described in 10^{-9} sec.—the time taken for light to travel 30 cm.—was clearly recorded. In this latter case the electron velocity in the recording jet was about half that of light, the transverse writing speed about one-fifth that of light.

Turning to the low-speed sealed-off oscillograph, Mr. Watson Watt enumerated the residual defects, mainly due to the gas content utilised as an aid to focusing, which still mar slightly the remarkably fine performance of modern tubes of this simple character.

The lecture was illustrated by demonstrations using eight oscillographs in all, a battery of five in parallel arranged around the lecture theatre, and three independent tubes of special construction. A demonstration of particular interest was the optical projection, throughout all the experiments, of the moving screen image from the central tube of the paralleled group on to a screen approximately two feet square, with a tenfold magnification. This projected image was clearly visible from the back of the theatre although an accelerating voltage less than 2,000 was used on the tube. There was a striking contrast between the red fluorescence of the 'port' member of the group and the brilliant green of the 'starboard' tube.

---

* The lectures are being published in the February issue of the *Journal of Scientific Instruments*.

In addition to experiments showing the applications of the oscillograph in radio research, Mr. Watson Watt exhibited a cinematograph film from the same field. The most novel section of the film might, he suggested, be called "Sturm über Europa", as it represented a single minute of the thunderstorm history of Europe. The places of origin of individual atmospherics—located by simultaneous cathode ray cinematography on a base-line Slough-Leuchars—were indicated by bright flashes on a dark map of Europe, the timing of the flashes reproducing accurately the times of incidence of the individual atmospherics. The film showed that, within a single half-minute of recording, lightning flashes in mid-Atlantic, the North Sea, Denmark, Germany, Hungary, the Balkans, and France had contributed to the stream of atmospherics affecting Great Britain.

The lecture concluded with demonstrations of the variety of colour and duration of afterglow in screen materials, of the control of brightness by a Wehnelt cylinder, and of the applications of oscillographs fitted with Faraday cages to operations in which oscillographic response and relay control are combined.

The oscillographs used in the demonstrations were lent by the manufacturers, Messrs. A. C. Cossor, Ltd.

TIME MEASUREMENT: OLD AND NEW

The last of the evening discourses at the Physical Society's exhibition was given by Mr. Hope-Jones on January 5 on "Time Measurement: Old and New". With the kind permission of Sir Henry Lyons, the director of the Science Museum, he was enabled to begin his lecture by exhibiting the Dover Castle clock, still going, although a relic of the fourteenth century. He showed lantern slides of the half-dozen known examples of this period, de Vick, Wells, Cassiobury, Salisbury, Porlock and Dinan, and expressed the hope that others will be found to have escaped the scrap-heap or restoration by a vandal clockmaker.

Mr. Hope-Jones traced the origin of the astronomical dial (a few of which survived the dissolution of the monasteries, such as Glastonbury, Wells, Wimborne and Hampton Court) from the Ptolemaic or geocentric conception of the universe, and showed models of Galileo's and Huyghens' escapements which harnessed the pendulum to wheelwork, thus bringing to a close the medieval period of 300 years during which the only known regulator for clocks and watches was the *Foliot* balance.

The halcyon days of English clock-making, inaugurated by Robert Hook, Harrison, Arnold and Earnshaw were discussed, and Mr. Hope-Jones deplored the fact that when Tompion and Graham were laid to rest in Westminster Abbey, the science of accurate time measurement died with them, or rather remained for two hundred years exactly in the condition in which they left it. He attributed this to the escapement, which had 'mesmerised' horology for so long, and showed how the "Synchronome" remontoire produces perfect freedom of the pendulum by coupling two together as 'master' and 'slave', a feat accomplished by Mr. Shortt's invention of the hit-and-miss synchroniser.

The extraordinary effects of the new standard of time-keeping set up by this clock were rapidly reviewed: how it caused the astronomers to invert their methods of producing rate charts; how it revealed nutation and necessitated a revision of the definition of time in the Nautical Almanac, and finally how the lunar period appeared in comparison with the crystal clock, although the change in the value of G only affects the rate by 2/10,000 sec. at maximum between lunar noon and midnight.

Prof. C. V. Boys has dubbed Mr. Hope-Jones as a modern Saint Athanasius, saying "this is the clock faith which, unless a man believe faithfully, he cannot be saved", subscribing to its articles himself, "with the possible reservation of some of its damnatory clauses". Whilst discouraging the use of the new synchronous motor clock for the time equipment of large buildings and institutions, Mr. Hope-Jones proclaimed the engineers of the electric light and power stations as the future time-keepers of the nation, and described means of assisting them to keep their turbo-alternators running true to average Greenwich Mean Time.

Annual Meeting of the Mathematical Association

THE annual meeting of the Mathematical Association was held in London at the Institute of Education on January 5 and 6. The most notable features of the meeting were the presidential address by Prof. G. N. Watson and a discussion on "The Study of Statistics in a School Course". Prof. Watson's address had the mysterious title of "The Marquis and the Land Agent; a Tale of the Eighteenth Century". It was revealed as a topic from the history of mathematics. The speaker regretted that as a pure mathematician he could not speak on some popular subject from the 'real' world of the applied mathematician. Neither could a popular discourse be made on those researches into singular moduli which had engaged his leisure during the past two years. Pedagogical problems he regarded as of secondary importance. Only a historical subject remained.

The Marquis of the title was the Italian mathematician Guilio Carlo, Count Fagnano and Marquis de Toschi (1682–1766). English textbooks refer to him as Fagnano and mention a theorem concerning elliptic arcs. The 'land agent' was the English amateur, John Landen (1719–90) who was in the service of Earl Fitzwilliam from 1762 until 1788. His name is familiar in 'Landen's transformation' for an elliptic integral.

The tale uniting these two was their work on rectifying elliptic arcs and manipulating the corresponding integrals. In 1691, Bernoulli had discovered that it is possible to find arcs of a parabolic spiral which are of equal length but are not congruent. Fagnano obtained similar results for the lemniscate, and enunciated the general theorem that if m is an integer, a quadrant of the lemniscate can be divided into 2^m or 3×2^m or 5×2^m equal parts. Amongst his results occur rudimentary forms of the addition theorems for elliptic functions. Many years later, Jacobi referred to the day on which a copy of Fagnano's works reached Euler as "the birthday of elliptic functions". Landen, in his "Mathematical Lucubrations" (1755) studied transformations of integrals, showing considerable ingenuity in obtaining forms convenient for calculation. This aspect was developed later by Legendre, Gauss and Ivory. Prof. Watson mentioned, in passing, that, in his opinion, mathematicians of the eighteenth century handled the technique of the calculus more skilfully than the technique of analytical geometry.

After this pioneer work, development took place on two very different lines. Legendre developed the elaborate, but unfruitful calculus of integrating expressions giving elliptic arcs, whilst thirty years later Abel and Jacobi developed the vastly more important concept of inverting such integrals, thus founding the theory of doubly periodic functions. One of time's revenges lies here. The first mention of this concept of inversion is in a manuscript by Gauss dated January 8, 1797. Had Legendre known of this, he would never have given the last part of his life to the futile labour of his "Traité des fonctions elliptiques". Yet Gauss's failure to announce his result was directly due to his treatment at the hands of French mathematicians when his memoir on arithmetical numbers was refused publication by the French Academy. After their humiliating refusal to publish this work, Gauss was loath to take any steps to publish during his own lifetime.

Prof. Watson mentioned some recent approximate formulæ for the perimeter of an ellipse, due to Peano (1887)—a mathematician usually associated with very different studies—and Ramanujan (1914). In connexion with his address an unusually complete exhibition of books on elliptic functions, arranged chronologically, had been compiled by Prof. Neville.

The discussion on "The Study of Statistics in a School Course" was opened by Mr. F. Sandon, headmaster of Plymouth Grammar School, who presented the unpopular view that the subject could have no place in the normal course. He suggested that the capabilities of pupils are so various and the intrinsic difficulties of the subject so real that little value would result. Few teachers appear to know much of the subject. Statistical principles can be applied to modify some topics in the arithmetic course, such as the teaching of averages and graphs of statistics, but work beyond this, such as probability or correlation, is too difficult or laborious. Mr. Tuckey of Charterhouse and Mr. Wright of Winchester gave evidence flatly contradicting this. With an average middle school form, a course of two hours a week has proved possible and profitable at Charterhouse. Frequency curves, probability, dispersion and correlation have been studied with some seriousness. At Winchester, rather abler boys with no examination in prospect have covered a systematic textbook course as far as Spearman's "Foot-Rule" for measuring correlation. The balance of opinion of the meeting appeared to favour testing these opinions as to the possibility of teaching statistics in schools.

Other papers discussed various topics. Dr. Smart of Cambridge traced the history and importance of the precession of the equinoxes. Dealing with the importance of accuracy in observation, he mentioned the recent discovery of the work of the Rev. John Hornsby, an eighteenth century Oxford astronomer. From Hornsby's observations it is possible to obtain the data showing the motion of the perihelion of Mercury—a phenomenon that was not satisfactorily explained until the present century. Work in school was dealt with by several teachers. Mr. Boon of Dulwich pleaded for more use of side-tracks such as history and puzzles in elementary mathematics. Mr. Robson of Marlborough showed the possibilities of parametric representation in the specialist course. A keen discussion followed Mr. Siddons's paper on "Learning Theorems in Geometry". Mr. Siddons suggested that learning theorems is not valuable until pupils have some skill in solving riders. Mr. Piggott of Dartmouth put forward a more real method of teaching relative velocity than that current in textbooks. The device of 'reversing a velocity' was shown to be quite unnecessary. Finally, the Rev. D. B. Eperson of Sherborne concluded a most successful meeting with a diverting account of Lewis Carroll's work as mathematician.

Annual Conference of the Geographical Association

THE annual conference of the Geographical Association was held at the London School of Economics on January 4–6, and at the Imperial Institute, South Kensington, on January 7. About five hundred members took part, provincial and Scottish branches being particularly well represented.

The retiring president, Dr. H. R. Mill, chose as the title for his presidential address "An Approach to Geography". In fluent and easy language, yet with a precision too often absent from generalisations, he traced the progress of the modern concept of scientific geography. He emphasised the steady conquest by man of so many of the natural factors of his environment and the evolution of the world of to-day, which may thus be free and open to the movements of mankind. But man, in conquering the natural barriers, has erected in their stead artificial barriers in the form of frontiers with their tariff walls and innumerable other restrictions. Thus the geographer cannot ignore the new, though artificial, factors of the environment and his work must interlock with that of the economist. At the same time, the problem is complicated by the fact that geographical factors are becoming more and more important in that, with the world improvement of transport and communications, it no longer pays a country to attempt the production of a commodity for which it is geographically unsuited.

This function of the geographer in helping to provide solutions for the complicated problems of the present day was further emphasised by Sir John Russell in his lecture on "Modern Changes in the Sources of our Food Supplies". One of the speakers at the annual dinner referred to geography as the 'most human' of all the sciences and to the appropriateness of meeting in the School of Economics, which was represented at the dinner by its director, Sir William Beveridge. The benefits to be derived from collaboration with allied sciences was further emphasised by a joint meeting with the Le Play Society, when an account of studies in Yugoslavia —the result of party visits led by himself and Dr. L. D. Stamp—was given by Mr. Arthur Davies.

The Association extended its welcome to Col.

Kenneth Mason, recently appointed professor of geography in the University of Oxford, who lectured on the exploration of the Himalaya, and to Lord Meston, whose first-hand account of contrasts in the Ganges basin threw many delightful sidelights on Indian geography.

The revival of interest in the land of Britain and its uses must inevitably be a feature of the next few years and the Association was given an account of the work of the Welsh Plant Breeding Station, Aberystwyth, in Prof. R. G. Stapledon's lecture on the improvement of hill grazings. A brief account was given of the progress also of the Land Utilisation Survey, now nearing completion.

Amongst the many meetings arranged for teachers, special interest was attached to the discussion of a model First Certificate examination paper drawn up by the Standing Committee of Secondary School Teachers. No new features not already commonly used in this examination were found suitable for inclusion, and suggestions made by some teachers present were nearly all negatived by others. Though taking little part in the discussion, a number of examiners were present and were doubtless relieved to find the meeting expressing the opinion that papers actually set by various examining bodies in recent years compare very favourably with the paper suggested by the Committee. Many teachers were clearly brought to realise the extreme difficulty of setting a paper to be answered by ten thousand candidates prepared by a thousand different teachers.

L. DUDLEY STAMP.

Calendar of Nature Topics

St. Hilary's Day. The depth of winter

January 14.—Although in the northern hemisphere the shortest day and least amount of insolation occur about December 21, the temperature of the air is maintained by the heat stored in earth and sea, and as this heat is given up, the average temperature continues to fall for nearly a month after the shortest day. This is expressed in the proverb:

"As the day lengthens,
So the cold strengthens."

The turn of the season is associated with St. Hilary's day in England and with St. Maur's day (January 15) in France. According to the smoothed ninety year averages at Greenwich, the coldest days of the year are January 12–14, all of which have the same mean temperature. The vagaries of our climate are, however, so great that in any one year the coldest day may fall on any date from mid-November to mid-March.

Winter Congregations of Birds

During January, Gilbert White noted the congregating of several species of British birds—in the order of their observation, skylarks, snow-buntings and chaffinches. He might have added, as equally characteristic of the season, fieldfares, redwings and mistle-thrushes, for the flocking together of the individuals of a species during the off-season when sex is at its lowest is a common occurrence. Of all the congregations, those of the chaffinch intrigued him most, first because the vast flocks which he saw contained many more birds than could be hatched in one neighbourhood, and secondly because the flocks seemed to be almost all hens. On the latter point he had been misled to some extent by Linnæus, who, thinking that "before winter all the hen chaffinches migrate through Holland into Italy", leaving the cocks behind, named the species *Fringilla cœlebs*. Although there is no such independent migration, it is true that there is a tendency for chaffinches to group in flocks in which one sex predominates, but equally mixed flocks are common enough. As regards the excessive numbers in the winter flocks, the explanation is that while we retain our native stock—for our British-bred birds do not seem to migrate—there are added to their numbers, immigrants from northern and central Europe which remain in Britain from about November until May, and birds of passage which make a temporary sojourn in Great Britain during their progress towards, and return from, south-western Europe.

Movements of Winter Flocks of Birds

It is generally stated that the winter flocks of chaffinches in Britain are nomadic, wandering from one area to another in search of food, and although it is certain that such as the great immigrant flocks of wood-pigeons move over the country from one feeding ground to another as food supplies become exhausted, an American experiment suggests that more has to be learned about the detailed movement of the winter congregations. Crowned sparrows (*Zonotrichia*), on their winter migration, arrive in late September on the campus at Stanford University, California, and leave on their northward migration in late April or early May. A combination of ringing, trapping, and staining the feathers with a distinctive oil colour dissolved in carbon tetrachloride, so that the members of a particular flock could be recognised in the field, led to some interesting results (John B. Price, *Condor*, 1931, p. 238). In the first place, individual birds, after their summer migration to the breeding quarters, which range from British Columbia to Alaska, frequently return to winter in the same district and are usually recaptured even in the same trap. In the winter of 1927–28, 197 golden-crowned sparrows (*Z. coronata*) were ringed at Stanford, and in the following winter after a lengthy migration 28 per cent were re-captured there, and many more may have returned which were not trapped. In 1928–29, 120 golden-crowns were re-captured which had been captured (ringed or recovered) at Stanford the previous year. Of these, 96 were taken by the original trap and only 24 were re-captured exclusively at other traps, although the traps were quite close together. Here is an indication not only of a fine sense of locality, but also of a certain flock association which remains constant in successive winters in spite of the intervening break-up of the breeding season.

A second remarkable discovery, revealed by the trapping of ringed birds and confirmed by the movements of artificially coloured birds, a standard colour having been adopted for each flock, was that there was practically no interchange of individuals between flocks. Although the two traps concerned with two distinct flocks were but 100 yards apart, only one case of the crossing over of an individual occurred. Further, none of the stained golden-crowned sparrows was seen 600 yards from the staining trap and most were observed within 400 yards of it. It would seem that if territory dominates the breeding *pair* during spring and summer, it dominates the *flock* and not the individual during the winter, to such a degree that each definite flock has its own almost exclusive range of about 15–20 acres.

Societies and Academies

London

Geological Society, Dec. 7. J. A. Douglas: Geology of the Marcapata valley in Eastern Peru. The broad zone of Devonian rocks which runs north from Juliaca forms the bulk of the cordillera of Vilcanota, and there is little evidence of the existence of Upper Carboniferous deposits, which cover so wide an area in the region around Lake Titicaca. An underlying unfossiliferous black shale series, probably of Silurian age, is the chief formation in the cordillera of Carabaya. The intermontane region presents a vast accumulation of glacial debris, derived from the now shrunken glaciers of the Vilcanota knot, a group of giant snow-covered peaks which, from the evidence of morainic material, must be largely of volcanic origin. The eastern flanks of the range disclose a great diversity of metamorphic rocks, chiefly andalusite and cordierite-hornfels, penetrated by intrusions of typically alkaline biotite-microcline-granite; while at the head of the Marcapata Valley occurs an interesting suite of coarse-grained, basic, hornblende rocks, probably of hybrid origin, with associated pegmatites. Farther down the river, dynamically metamorphosed rocks are encountered chiefly granitoid gneisses and amphibolites, with associated paragneisses of sedimentary origin. L. R. Cox: Fossiliferous siliceous boulders from the Anglo-Egyptian Sudan. The paper describes a series of scattered eroded boulders of a hard, splintery, fossiliferous, chert-like siliceous rock found at two localities in the Berber district of the Anglo-Egyptian Sudan. Many of the boulders consist of rounded or subangular grains of opal or opal-derived chalcedony of various sizes with clear quartz and chalcedony in the interstices between them. On account of their large content of opaline silica it is considered that they are a product of secondary and probably surface silicification, and have been formed from, and within, a deposit once spread over the district. Except for one puzzling specimen which may be a fragment of a *Pinna* shell (a marine lamellibranch) and some obscure remains, apparently of plants, the fossils enclosed in the boulders are all non-marine gastropods. A Lower Tertiary age can be assigned with confidence to the fauna, on account of the presence of the genus *Pseudoceratodes*; the precise age may be Upper Eocene or possibly Lower Oligocene.

Paris

Academy of Sciences, Nov. 21. Ch. Lallemand: The world crisis and the gold standard. The author suggests the gram of gold as an international monetary standard, in which all financial contracts should be expressed. A. Cotton: Remarks on a note of M. Schérer on circular magnetic dichroism and magnetic rotatory dispersion. The author had earlier made experiments similar to those recently described by Schérer, but as the magnetic fields were only about one tenth those used by Schérer, no certain proof of circular magnetic dichroism could be obtained. The history of the subject is reviewed and discussed. Georges Claude: The manufacture of commercial oxygen. A description of recent progress in the preparation of oxygen by the fractional distillation of liquid air, especially the improvements introduced by Frankl. J. Schokalsky: The circumnavigation of the François Joseph archipelago by the north. An account of a voyage around this archipelago in a small vessel, the *Knipovitch* (motor 125 h.p.) under Capt. S. Popov. The author's view of an improvement in the polar climate, possibly temporary, was confirmed. Lucien Daniel: The variations of *Helianthus Dangeardi* at the fifth generation. Bertrand Gambier: The congruence of circles: focal points and focal surfaces. Lucien Chamard: Certain singular points of ensembles equidistant from a point ensemble. Marcel Brelot: The trend of sub-harmonic functions in the neighbourhood of a point, singular or not. Arnaud Denjoy: The characteristics of the tore. Jacques Devisme: Some applications of hypergeometric functions. G. Bourion: A class of Taylor's series. Robert L'Hermite: Plane rectangular pieces of small thickness submitted to peripheral pressures situated in their plane. Bernard Lyot: The direct observation of solar prominences at Meudon. The direct method of observing the prominences has advantages over the spectrohelioscope or spectroheliograph, but up to the present has only been used during eclipses. The possibility of directly observing the protuberances was proved by observations made on the Pic du Midi in 1930 and 1931. By a careful study of suitable screens it has now been found possible to make good observations at the Meudon Observatory. An exposure of one second gives a good solar image (8 cm. diameter) as against several minutes required by the spectroheliograph. Hence by means of kinematograph films it is now possible to study the complex movements of prominences. Y. Rocard: The formation of negative ions according to quantum mechanics. I. I. Agarbiceanu: The absorption of the fluorescent light of iodine by the same vapour. M. Scherer: The circular magnetic dichroism and abnormal magnetic rotatory dispersion of solutions of cobalt chloride. Curves are given showing the ellipticities and rotations as functions of the wave-length. The large Bellevue electromagnet was used to obtain the magnetic fields. P. Jacquet: Study of the strains in electrolytic copper deposited in the presence of colloids. In a previous communication on the same subject the colloid used was gelatine: the present note describes similar experiments carried out with other colloids, serum albumin, gum arabic, gum tragacanth and dextrin. The results are summarised in graphs. H. Forestier: The influence of the magnetic field on the electrolysis of nickel salts. The rate of deposit of nickel by electrolysis in acid solutions diminishes as the strength of the magnetic field increases: in solutions of zinc or copper the magnetic field causes a slight increase in the velocity of deposit of the metal, due possibly to the influence of the convection currents of the electrolyte. Picon: Thorium sulphide. This sulphide can be prepared by heating the oxide, placed in a graphite boat, in a current of hydrogen sulphide at 1200° C. The reaction is complete after one hour, and the temperature is then raised to 1600° for thirty minutes. The product is thus melted and is free from oxygen and carbon. The physical and chemical properties of the thorium sulphide are given. Mme. Ramart-Lucas and Mme. M. Grumez: The colour and structure of oximes and semicarbazones. The absorption in the ultra-violet of oximes and semicarbazones shows that not only can these substances exist in two stereochemical forms, but also in two isomeric forms in which the functional group is different. Charles Dufraisse and Raymond Buret: Researches on the dissociable organic oxides. Extension of the methods for the preparation of the rubrenes. Application to the synthesis of a dichlordiphenylrebene, $C_{30}H_{18}Cl_2$. The practical preparation of this substance starting from dibenzoylmethane. S. Goldsztaub: The crystalline structure of gœthite. Jacques Fromaget: New observations on the geology of the stanniferous region of Nam Pha Thène (Laos). P. Geoffroy: The probable age of the Doui series in the Middle Chélif (Algeria). Ch. Joyeux, J. G. Baer, and J. Timon-David: Researches on the evolutive cycle of the trematodes belonging to the genus *Brachylæmus*. Henri Jean Frossard: The measurement of the ventricular pressure by the pulsatory method. Georges Bourguignon and Socrate Eliopoulos: The classification of different ions in natural chemical families by their vaso-motor action in trans-cerebral dielectrolysis. P. Kucharski: Researches on the structure of the vowels. A. Girard, G. Sandulesco, A. Fridenson, and J. J. Rutgers: A new crystallised sex hormone. A new hormone, equilenine, has been isolated from the urine of pregnant mares. 1·5 gm. of the purified hormone were obtained from 52 tons of urine. It is a ketone of the composition $C_{18}H_{18}O_2$.

MELBOURNE

Royal Society of Victoria, Oct. 13. C. Oke: Australian Staphylinidæ. Alan Coulson: Diabase rocks at the You Yangs near Geelong. Boulders of diabase are recorded from this locality; when examined microscopically they show uralitisation of a similar character to that of the epidiorite at Ceres and Dog Rocks; it is probably of Cambrian (Heathcotian) age. The occurrence lies in an axial line passing through the Colbinabbin Range, Mount William and Ceres. Alan Coulson: The older volcanic and Tertiary marine series at Curlewis near Geelong. This series of basalts and tuffs underlies Tertiary marine clays and limestones of a probable Janjukian age. Faulting and folding have affected the area and are illustrated in plans and sections of the beach and cliffs at Curlewis. Cause of earth movements not apparent, but are tentatively correlated with the (?) newer Pliocene tectonics of the Geelong district. W. M. Holmes: The Mornington earth tremor of Sept. 3, 1932. The brief duration of this earth tremor did not permit the identification on the seismogram of the various phases of the earth waves with any degree of accuracy. The epicentre was therefore determined by two hundred replies received from a questionnaire prepared on a basis of the modified Mercalli scale of intensities. A numerical value was assigned to each locality, and lines and bounding areas of equal intensity were drawn on the map. These lines indicated an epicentre at 38° 15′ S. and 145° E., a position west of Mornington in Port Philip Bay.

ROME

Royal National Academy of the Lincei: Communications received during the vacation. G. A. Crocco: The stability of 'instrumental' flight. The problem of the stability of an aeroplane in 'blind' flight may be defined by three equations treating of the perturbed motion of the baricentre, and by three 'instrumental' equations controlling the perturbed motion about the baricentre. G. Armellini: Some theorems on the problem of two bodies of decreasing masses. Q. Majorana: A new photoelectric experiment. When exposed to the action of an intense pulsating radiation, very thin sheet metal undergoes an appreciable increase in its electrical resistance which does not appear to be due solely to the thermal action of the light. The results of experiments with silver thin enough to show a distinct blueish transparency indicate that, under the conditions mentioned, the resistance of the metal is subject to pulsation, the mean value being somewhat greater than that observed in the absence of the light. T. Boggio: The curvature of lines of varieties. Various relationships—some of them not previously observed—between the curvature and torsion of a geodetic and the curvature of one of its plane projections, are deduced. H. Chapiro: The transplantation of the parallel transport. L. Laboccetta: The effective integration of discontinuous functions (2): *Reduction to normal types and fundamental integrals.* All ordinary discontinuous functions may be reduced, without altering the value of their integrals, to certain fundamental types which admit of easy integration. G. Lampariello: The equation of the transverse vibrations of an elastic rod supported at its ends. W. S. Urbanski: The integration of Hamilton's equations for infinite time. V. Hlavaty: Differential projective invariants of a curve in the projective space P_{n-1} ($n =$ or > 3). B. Segre: The conditions for the regularity of a linear system of forms. M. Cimino: The laws of the areas of an Einsteinian motion considered in ordinary Euclidean space. G. Agamennone: The supposed repercussion, at the antipodes, of the eruption of Krakatoa in 1883. R. Einaudi: Magnetic behaviour of the oxygen molecule. The magnetic behaviour of the oxygen molecule in fields of the order of magnitude of 10^4 gauss is studied theoretically, and the results of experiments by Schnurmann on magnetic deviation are found to be justified on theoretical grounds. P. Straneo: The unitary theory and absolute geometrisation. G. C. Wick: The motion of an electron in a crystalline lattice. Taking into account the resonance forces due to the identity between a conducting electron and the bound electrons of the lattice, the energy levels of an electron in a lattice are calculated as a first approximation. A relative maximum of the energy for zero velocity of the electron is revealed. C. Antoniani and F. Zanelli: Investigations on the cholesterol of the human brain. The molecular magnitude and the percentage composition of human cerebral cholesterol are the same as those of biliary cholesterol. Whether obtained from the fœtus or from the adult, the cholesterol of the brain and certain of its derivatives exhibit slightly higher melting points than the product from the bile, and similar differences are observed in the specific rotation. These results are not, however, regarded as evidence of the non-identity of the two cholesterols. A. Baroni: Lithium alloys. (1) Thermal and X-ray analysis of the system lithium-tin. The diagram of state derived from the thermal analysis indicates the existence of the three compounds, Li_4Sn (M.P. 684°), Li_2Sn_5 (M.P. 483°) and $LiSn_4$, and of three eutectic points at 458°, 320°, and 214°, corresponding respectively with 35, 58, and 94 per cent (atomic) of tin. The X-ray analysis permits of the identification of the compounds $LiSn_4$ and Li_2Sn_5, but the photograms obtained by the powder method do not allow the structures of these compounds to be calculated. F. Scarsella: The diffusion of the strata with *Posidonomya alpina* in the Central Appennines. A. Cavinato: Thermal expansion in crystals and Haüy's law. The validity of Haüy's law for a crystal expanded by heat is demonstrated. B. Monterosso: Cirrepedological studies (9). Anærobiosis in *Chthamalus stellatus* Ranzani. Gabriella Pastega: Power of recovery and growth of the cyclopean eyes of 'lithium' embryos of *Rana esculenta*.

Forthcoming Events

Monday, Jan. 16

ROYAL GEOGRAPHICAL SOCIETY, at 5.—Dr. L. J. Spencer: "Meteorite Craters as Topographical Features of the Earth's Surface".

KING'S COLLEGE, LONDON, at 5.—Prof. G. Temple: "The Principle of the Quantum Theory".

UNIVERSITY COLLEGE, LONDON, at 5.—Dr. L. E. Bayliss: "The Respiratory Functions of the Blood" (succeeding lectures on Jan. 20, 23 and 27).

Tuesday, Jan. 17

ROYAL INSTITUTION, at 5.15.—Prof. J. C. McLennan: "Low Temperatures and Low Temperature Phenomena" (succeeding lectures on Jan. 24, 31, and Feb. 7).

Wednesday, Jan. 18

UNIVERSITY COLLEGE, LONDON, at 5.30.—H. M. Adams: "Bibliography in Cataloguing".

ROYAL SOCIETY OF ARTS, at 8.—Olaf F. Bloch: "Recent Developments in Infra-Red Photography".

ROYAL MICROSCOPICAL SOCIETY, at 5.30.—(Annual General Meeting). Mr. Conrad Beck (Presidential Address): "Microscope Illumination with Transmitted Light".

ROYAL METEOROLOGICAL SOCIETY, at 7.40.—(Annual General Meeting). Prof. S. Chapman (Presidential Address): "Atoms, Molecules and the Atmosphere".

Thursday, Jan. 19

ROYAL INSTITUTION, at 5.15.—Prof. J. B. S. Haldane: "Recent Advances in Genetics" (succeeding lectures on Jan. 26, Feb. 2 and 9).

Friday, Jan. 20

ROYAL INSTITUTION, at 9.—Sir William Bragg: "The Crystals of the Living Body".

UNIVERSITY COLLEGE, LONDON, at 5.30.—Dr. W. W. Gregg: "The Descent of Manuscripts" (succeeding lecture on Jan. 27).

UNIVERSITY OF LONDON (at University College Hospital Medical School, University Street, Gower Street, W.C.2), at 5.15.—Prof. Max Bergmann: "The Chemistry of Proteins" (succeeding lectures on Jan. 23 and 24).

The Arts in Industry

THE view that mass production necessarily tends to a mechanisation of industry and society, although stoutly challenged by such leaders of industry as Mr. Henry Ford and Mr. E. A. Filene, finds sufficient support to emphasise the importance of recent surveys of the position of industrial art in Great Britain. Indeed the fact that Mr. Ford and Mr. Filene base much of their argument on the opportunity afforded by increased leisure for developing the arts to some extent accentuates the importance of a critical examination of the position of art in relation to industry, and necessitates some effort to determine whether or not under modern industrial conditions mass production involves so little intelligence or craftsmanship in its processes that the outcome is the staffing of industry mainly by cheap people of low intelligence. If, indeed, such is the necessary consequence of power production, the mechanisation of society may be too high a price to pay for the advantages which mass production confers. Ruskin's picture of the industrialisation of England has to-day an application and a validity which is far from being confined to the significance which he first attached to it: "Unless you provide some elements of beauty for your workmen to be surrounded by, you will find that no elements of beauty can be invented by them."

It would be unfair to charge modern industry, in spite of mass production, with indifference to æsthetic considerations. Attention has already been directed to the relations of art and industry in the important reports issued in recent years by the Balfour Committee on Industry and Trade. In "Factors in Industrial and Commercial Efficiency" the Committee points out that the difficult problems of art and design which have emerged from the disturbing and sometimes disastrous effect of mechanisation, with its sub-division of employment and mass production, on industrial art by breaking up the old craft traditions, revolutionising technique and severing or weakening the close relations which previously existed between designer and executant, have scarcely yet been fully faced. Since success in international competition depends more and more on quality of output, an adequate solution of these problems is of critical importance to the position of British trade.

A survey of the present position of British industries in respect of industrial art contributed to the same report by the British Institute of Industrial Art stresses the opinion that modern tendencies in certain trades to sever design from manufacture and to rely unduly on foreign sources for the former involve serious danger to the well-being of British industries and art. The survey was limited to the position of industrial art in relation to productive industry, but the growing gap in modern industry between the original producer and the ultimate consumer makes its position in relation to the distributive trades likewise of crucial importance. The final report of the Committee on Industry and Trade similarly confined its observations mainly to productive industry, expressing the opinion that the situation was far from satisfactory in view of the vital importance of fine design and workmanship in maintaining and enhancing the reputation and attractiveness of many classes of British products.

A good deal of similar evidence was in existence on the relations of art and industry when in July 1931 a Committee was appointed by the Board of Trade under the chairmanship of Lord Gorell on the production and exhibition of articles of good design and every-day use. The report of this Committee was published in March 1932 but its excellent recommendations are still awaiting action, and this hiatus appears to be partly responsible for prompting a recent suggestion by Mr. J. A. Milne, in his inaugural address to the Royal Society of Arts on beauty in industry, for the establishment of a ministry of fine arts. Mr. Milne urged that reasons of economy have weakened all the recent tentative Government efforts to deal with this important subject and that, without effective financial backing such as a ministry of arts could supply, there was little prospect of improvement.

The terms of reference of the Gorell Committee, like the pleadings of Mr. Milne, recall the arguments of John Ruskin, one of the pioneers of the movement in the latter part of the nineteenth century to foster healthier relations between creative design and craftsmanship, and in particular his assertions that the wisdom of art consists in its unselfish devotion to the service of men, and that art does its duty "in completing the comforts and refining the pleasures of daily occurrence and familiar service". The chief recommendations of the Committee are indeed concerned with the promotion of exhibitions of industrial art organised to improve the taste of designers, manufacturers, distributors and the general public by the display to the best advantage of beautiful modern manufactured goods, due regard being paid to the purchasing power of the householder of moderate means. The establishment of a central body with executive powers, responsible for such exhibitions and in close association with the Department of Overseas Trade, the enlistment of the support of local art museums, and the co-ordination of the activities of the British Institute of Industrial Art with those of the new national organisation, are all recommendations directed to this end.

The above proposals are perhaps those which are most likely to involve direct expenditure and which Mr. Milne had chiefly in mind in his appeal for a ministry of fine arts. No less significant, however, than a new exhibition policy are other concurrent measures of general policy advocated by the Committee. Prominent among these is the initiation of steps to terminate the divorce of 'fine' and 'industrial' art and "to secure that numbers of the leading and most promising artists and craftsmen of the day should be encouraged to turn their energies into the industrial manufacturing field and that they find there as secure, remunerative and honoured a career as in painting and sculpture". The report continues in words which will have a familiar ring to scientific workers: "Unless first rate industrial work by artists receive national recognition in future to the same extent as the best work in the field of painting and sculpture many of the best artists will continue to avoid an industrial career".

Closely related is the question of the improvement of art education of the country, itself, which is one aspect of the general problem of improved and closer relations between education and industry and as such falls within the purview of inquiries recommended to be undertaken through the British Institute of Industrial Art. It is clear that much remains to be done in order that teachers and students in art schools should have a clear conception of the requirements of industry, and industrialists a first-hand knowledge of these schools.

While, however, these measures should help to promote the supply of competent designers and artists, the question of demand must not be overlooked. The supply is unlikely to be adequate in either quality or quantity unless the demand for such services is sufficiently widespread and the appreciation awarded them sufficiently generous either in remuneration or status. From this point of view it is essential that the nation should, as urged by the Gorell Committee, face, in the public, secondary and elementary schools the problem of making the understanding and enjoyment of beautiful things an essential part of the day-to-day life of the school. It is only from the vision and training thus imparted that we can expect either in leisure or working hours a general level of artistic judgment and appreciation sufficient to resist any untoward effects of mass production.

It is indeed here that we touch on the fundamental problem which even in the Gorell report scarcely receives expression. Valuable as are the results already attending what is generally known as the 'arts and crafts movement', in the main the products of this movement have scarcely been within the regular purchasing power of consumers of moderate means. The movement has largely been concerned with the encouragement of handicraft and has not penetrated the processes of modern industry. A reversion to handicraft could not solve the problem of beautifying articles of common use within the purchasing power of the ordinary consumers and the technique of handicraft differs fundamentally from that of industrial manufactures. It is this field which has now to be captured for art. We have to face the task of expressing beauty in the materials and products and processes of modern industry even under the conditions of mass production. The production of goods in quantity is not necessarily a bar to the production of articles intrinsically beautiful. Mass produced goods commonly lack artistic merit because insufficient attention has been devoted to the design, to the materials of which the product is made or the purposes to which it is to be put—in a word, because the manufacturer has been concerned more with imitating the past than discovering new methods of artistic expression for his new powers and materials.

The reports to which we have directed attention pose fundamental problems which even in days of financial stringency cannot be shelved. For certain aspects of them the scientific worker himself must accept responsibility, and it is indeed only as he works in closer alliance with the designer and artist that we can hope for a full solution. Science has once more set mankind the task of harnessing new forces not merely to utilitarian but also to æsthetic purposes, and in the advent of an age of leisure the latter assume even greater importance. The man of science has much to contribute to the full understanding of the properties of the materials of industry and the processes by which they are worked. The artist has to transmute the material and the processes so that the outcome may be a product which ministers to man's artistic and æsthetic needs as well as to his material needs or comforts—"beautiful and quaint in design but also adapted for every day service and decorous in humble and secluded life". The Gorell Committee in its report does well to stress that note of service upon which both art and science depend, in which they have their strongest common bond and most splendid spur of rivalry in their contribution to the amelioration of the human race.

A Vanished World

Biographical Fragments. By Sir Arthur Schuster. Pp. xiii + 268 + 8 plates. (London: Macmillan and Co., Ltd., 1932.) 10*s.* 6*d.* net.

THE world of 1851, the birth year of Arthur Schuster, differed almost *toto caelo* from the age which has witnessed the publication of these biographical fragments. Posting as a means of travel was not altogether a thing of the past; the electric telegraph was still a novelty; the telephone had not yet appeared upon the scene. In the England of that era, shopkeepers in the capital still lived over their shops; merchants drove into the city in horse-drawn carriages, or rode in on horseback; for sixteen years to come malefactors were strangled outside Newgate in the presence of roaring crowds.

Of this civilisation, Frankfort, Schuster's birthplace, was a fascinating microcosm. The confederacy of German States which ensued on the break-up of the Holy Roman Empire had its Diet located at Frankfort, which in consequence took on something of an international character. On the outbreak of the war between Austria and Prussia in 1866 the city declared its neutrality but nevertheless had to submit to the entry of the triumphant Prussian troops; and Sir Arthur, from first-hand knowledge, draws a most graphic picture of this vanished world with its clanking dragoons, its whispering statesmen and ambassadors and, towering over all, the vast figure of Bismarck, then in his most arrogant *Blut-und-Eisen* mood.

Schuster tells us, too, something of his school-days in Frankfort, of his life as a student at Geneva and of his early days in England when, despite his longing for a scientific career, he found himself, an apprentice in the firm of Schuster

Brothers, copying letters and checking accounts in their office in Sackville Street, Manchester. It is not without a smile, too, that we read of the house taken by his father at Lytham under the impression that that homely Fylde seaside village was the Nice of England. A scientific career being decided upon, he gives us some account of the Quay Street period in the development of Owens College, of his wander-years, and of the circumstances that led to his taking charge of the eclipse expedition to Siam in 1874. Of this expedition and of its sequel, a journey through India, we have a most interesting and vivid account, and then, when we are looking forward to the tale of that splendid outburst of activity which marked Schuster's tenure of the chairs of applied mathematics and of physics at Owens College, the curtain rings down on the main theme, and the remainder of the book is concerned with a series of episodes and a number of admirably drawn sketches, which appeared originally in NATURE under the title "Biographical Byways", of eminent men of science of a generation that has gone.

The fragments that fall from Sir Arthur's table provide better fare than many another man's banquet, and we are most fortunate in possessing these skilfully etched portraits, giving life to many a personality otherwise but the shadow of a name. We see Henry Wilde, one day telling Schuster that he was unfit to be a university professor, the next day making amends for his hasty words by a present of hothouse grapes; Joule, receiving his manuscript rejected by the Royal Society, and envisaging a committee of rejection who should say "What good can come out of a town where they dine in the middle of the day"; and Balfour Stewart, of whom Sir Arthur gives a most sympathetic and understanding account, remarking "every billet has its bullet", after reading a letter from the Principal of the College in which the sting was distinctly in the tail. Leverrier, Boltzmann, Kirchhoff, Bunsen, Weber, Helmholtz, Reynolds, Stokes .... it is a remarkable gallery, and we are very much in Sir Arthur's debt for these studies sketched with both kindliness and insight; specially valuable are the accounts of Wilde, Stewart, Boltzmann, and Reynolds.

But we miss the story of Joule's Stone Ales!

Of the minor episodes, the tale of the thief and the barograph is not without human and scientific interest. A worker in the laboratory missed coins from the pocket of a coat which he left hanging overnight. Suspicion fell on a charwoman and a night-watchman, who visited the room at different times. A decoy coin was left in the coat pocket, so arranged that its removal would break a simple circuit and cause the pen of the barograph to make a jerk in its time record. The experiment was completely successful; the honour of the charlady was vindicated; and the peccant (and, we trust, repentant) figure of the night-watchman vanishes into the mists of forty years ago.

We close the volume with regret; not the least valuable of the impressions which have remained is that of the author himself, a great genius, versatile, kindly, humorous, and charitable; one who has seen much, and suffered not a little; who has followed the scriptural injunction to prove all things, and hold fast to that which is good. May we express the hope that he will find himself able to unfold to us the story of the development of the Manchester school of physics—a story which none can tell as he can, and in which he himself has played so great a part?

ALLAN FERGUSON.

Invertebrates

The Invertebrata: a Manual for the Use of Students. By L. A. Borradaile and F. A. Potts. With Chapters by Prof. L. E. S. Eastham and J. T. Saunders. Pp. xiv + 646. (Cambridge: At the University Press, 1932.) 25*s*. net.

THIS volume has been prepared for the use of students who have completed a year's study of zoology and are entering upon an advanced course. The book opens with an admirable introduction to the study of the structure and biology of the Protozoa, after which follows the systematic consideration of the four main sub-divisions, including a scheme of classification and references to the special points exhibited by representative examples. This chapter is especially praiseworthy for the attention devoted to free-living forms. The student tends to stress the parasitic Protozoa and this account provides a most useful corrective, and he who reads and digests this chapter of 109 pages will have acquired a sound and balanced basis of knowledge of the Protozoa.

A brief account of the sub-kingdom Parazoa (Porifera) follows and the rest of the volume is devoted to the invertebrate Metazoa and to two sub-phyla of the Chordata—the Enteropneusta and the Tunicata. For each of the more important phyla or sub-phyla a concise definition is given and is followed by observations on the general structure and development; the sub-divisions are defined, a representative example is usually described and references made to other genera which serve to illustrate special points in anatomy, life-history and biology.

The chapters on Crustacea (85 pp.) and insects (60 pp.) may be mentioned for their excellent treatment of the subject and for the quality of the illustrations.

The author of the chapter on Nematoda, in a brief discussion on the systematic position, holds that the simple structure of the nervous and muscular systems and the absence of vascular system are signs of a lowly origin and not of degeneration, and that there is no real connexion between these worms and the Arthropoda. He points out that the Nematoda present no signs of segmentation or appendages, the cuticle is of an entirely different chemical nature in the two phyla and the loss of cilia in the Nematoda is certainly secondary.

The text is supported by well-chosen illustrations, mostly in line, many of which are either original or are drawn from recent memoirs. The figure of the larva of *Echiurus*, from Hatschek, which shows the septa of transitory segments, would have been better replaced by one of Baltzer's representing the mesoderm as unsegmented, as it appears actually to be.

The work has been carefully planned and the authors have been at great pains to arrive at a fair balance of its principal parts. They state that the choice of examples has been difficult and that they have not been able to include all they could have wished. The omission of the Mesozoa is probably justifiable, but whether for example *Gordius* with its interesting life-history should have been entirely ignored is more doubtful. The authors have imposed on themselves a restriction in extent of the text which in places is rather severe, for example, the Hydrocorallinæ are dealt with in twenty lines, the Gephyrea in twenty-three and the Phoronidea in a dozen lines of text (but for each group there are also one or two illustrations with adequate legends), and of the Heteropoda only *Pterotrachea* is mentioned and of the Pteropoda only *Cavolinia*. It is, of course, recognised that to bring an account of the Invertebrata within the compass of a single volume of 600 pages compression is necessary, and it must be admitted that the authors have dealt on the whole judiciously with the conflicting claims for space of the different groups.

Errors are remarkably few and unimportant, and the proof-reading has been effective so that misspellings are very scarce. It should, however, be noted that *Ancylostoma*, not *Ankylostoma*, is the officially recognised form of this generic name. The authors are to be warmly congratulated on a work which is concise, accurate and adequately illustrated, and is a compendium of the most significant knowledge on invertebrates.

A New Surrey Flora

Flora of Surrey: being an Account of the Flowering Plants, Ferns and Characeæ, with Notes on the Topography, Climate and Geology, and a History of the Botanical Investigation of the County. By C. E. Salmon. Edited by W. H. Pearsall. Pp. 688. (London: G. Bell and Sons, Ltd., 1931.) 42*s*. net.

ALL those interested in British plants will welcome the appearance, after so many years' delay, of this new "Flora of Surrey". At the end of last century, W. H. Beeby was working at a new "Flora" of the county, but he did not complete his project and, in 1908, handed his manuscripts over to the late C. E. Salmon. His untimely death unfortunately prevented Salmon, in turn, from finishing the "Flora" and the volume now appears under the editorship of Dr. W. H. Pearsall, who is responsible for the introductory chapters and about one-third of the genera. The greater part of the work, however, is Salmon's, and the volume, with his portrait as a frontispiece, will remain as a lasting memorial to his unrivalled knowledge of the British flora.

There are excellent introductory chapters on the topography, climate, geology and botanical history of the county, together with a very full list of the authorities consulted. The "Flora" itself is, on the whole, admirably arranged, and especially valuable are the taxonomic notes and personal observations at the end of many of the species entries. It seems, however, an unnecessary waste of space to quote pre-Linnean names under each species; sometimes these occupy two or three lines and do not add to the value of the work. Under *Polygala* there is a reference to an appendix containing a key to the British species; no such appendix appears, however, to be in the volume.

The botanical value of the "Flora", as was to be expected from the authorship, is considerably greater than that of many works of a similar kind. Full treatment is accorded to critical genera and, in most cases, their distribution in the county is worked out in detail (for example, Batrachian *Ranunculus*, *Viola*, *Epilobium*, *Rubus*, *Rosa*, etc.). A useful feature is the constant reference to the literature of difficult groups. It is to be regretted, however, that these references do not include work on experimental and genetical lines as well as purely systematic papers. Under *Erophila*, for example, the work of Rosen and Winge might have been mentioned as well as that of Jordan; and under *Hieracium* there is no reference to Ostenfeld's researches on the apogamy of the genus. In omitting work of this type an opportunity has been missed of bringing into closer touch the old and the new schools of taxonomy. Unless this can be done, no further advance in our knowledge of the British flora is possible.

This, however, is a general criticism, applicable, unfortunately, to a great deal of the work on the British flora during the last thirty years, and does not prevent the volume from being one of the most attractively produced and valuable of our county 'floras'. The illustrations of places of botanical interest in the county and the two maps add considerably to its interest, and also, unfortunately, to its price, which is surprisingly high, even for a work of such limited circulation. Dr. Pearsall is to be congratulated on bringing to successful completion a work which has passed through so many vicissitudes during the last forty years.

Practical Organic Chemistry

Laboratory Methods of Organic Chemistry. By L. Gattermann. Completely revised by Heinrich Wieland. Translated from the Twenty-second German Edition by Dr. W. McCartney. Pp. xvii+416. (London: Macmillan and Co., Ltd., 1932.) 17*s*. net.

THIS is one of the classic textbooks of the organic chemist; there can be few who have not made use of it at the beginning of their manipulative training even in Great Britain, and the reviewer can plead guilty to struggling with the first edition, dated Heidelberg, August, 1894, in the original German in his student days. In issuing the nineteenth edition from Freiburg in 1925, H. Wieland, the successor to Gattermann, emphasised the fact that the equipment which sufficed during the last three decades has now become insufficient for those who desire to work at present-day problems, so that in rewriting the book the theoretical and practical requirements have been deliberately increased. We now have the twenty-second edition dated from Munich in July, 1930, with the English translator's date of April, 1932, which shows many changes, all directed to place the student in contact with modern fields of inquiry. Thus, two enzyme preparations have been included, and a biochemical flavour, showing the trend of the times, is also imparted by the preparation of natural compounds, such as furfural, glucose, arginine, nicotine, hæmin and the constituents of bile.

The number of preparations is, of course, in excess of what any student can complete in his course of about a year's training—in Munich it is usual for the student to carry out fifty to sixty preparations, as well as some six or eight from the original literature. The translation into English appears to be well made; and this new edition will be welcomed by students of practical organic chemistry unfamiliar with the German language. Serious students ought, however, to work through such a book in the original German—in no other way can they obtain so easily the essential knowledge of the construction and vocabulary of chemical German.

It would be attractive to use the first and the newest editions as the basis for moralising on the advances in organic chemistry during thirty-six years and on the method of teaching it, but lack of space prevents this being done here. At least it is more important to-day than ever that the worker must be a practical manipulator of the highest skill; and Gattermann's course of work is admirably designed to attain that end.

E.F.A.

On the Roof of the Forest

A Naturalist in the Guiana Forest. By Major R. W. G. Hingston. Pp. xiii + 384 + 16 plates. (London: Edward Arnold and Co., 1932.) 18*s*. net.

THE treetop canopy of the Amazons forest has always attracted the attention of naturalists; but hitherto the difficulties of exploration in this 'forest above the forest' have been thought to be almost insurmountable. The success of Major Hingston and his colleagues of the Oxford University Expedition to Guiana was due, not only to good organisation but also to perseverance and enterprise. Most of the party were young and with no previous experience of the tropics; and it says much both for the fine discipline of modern youth and for the wisdom of their leader that they lived successfully under canvas for months, thus disposing once again of the old idea of the dangers of camping in the jungle. In fact, such was the excellent organisation that we are told: "We always if we wished it could have a hot bath daily, and we always had our meals off a clean tablecloth."

The book is made up rather unevenly of two parts. The first, which contains an account of the general work of the expedition, is the most interesting and contains vivid descriptions of the forest, which, unlike the perorations of some other writers on the subject, never flush to 'precious purple'. The story of the attempts to establish a footing in the treetops makes exciting reading. Rather surprisingly, the arboreal ants and bees did not prove so ferocious as anticipated; and the rope-throwing rockets and other apparatus were less efficacious than the more primitive methods of the climbing Indian. Observation posts were planted as high as 120 feet; and the records obtained demonstrated what had previously been only suspected, namely, the well defined vertical distribution of life in the trees. For example, it was found that moths dominated the night fauna of the forest at ground level, and Hemiptera in the treetop roof. There remains a rich field for investigation into the different ecological factors —light, humidity, etc.—which condition animal life in the various zones.

The second part of the book, which deals with specific observations chiefly on the protective devices of spiders and caterpillars, is grafted a little clumsily on the first. Major Hingston is a whole-hearted believer in the mimicry theory, and he gives here a number of instances that came under his notice in Guiana. Most of them are new, all of them are interesting, but the section on spiders' snares overweights the book a little and would be better if abridged. Mimicry, having held the field for years against assaults on the theory of natural selection, has recently been sharply challenged; and new instances, if they are to help the case, must be beyond cavil. From this point of view the example of the Ascalaphid on p. 281 is of doubtful value, and that of *Laternaria* with its 'alligator-like' head never seems very convincing.

The book is illustrated by some excellent line drawings of the devices that the author describes; and by some adequate, though not outstanding, photographs of the forest.

M. D. B.

Short Reviews

(1) *Patents, Trade Marks and Designs: their Commercial Aspect and Development.* By Charles Waldron Thomas. (The Nutshell Series, Vol. 1.) Pp. 88. (London: Ocean Publishing Co., 1932.) 4*s*. 6*d*. net.

(2) *British Patents and Designs Statutes as Amended and Consolidated to 1932.* With an Introduction and Index by H. J. W. Bliss. Pp. viii + 126. (London: Stevens and Sons, Ltd., 1932.) 4*s*. 6*d*. net.

(1) This book is remarkable, and probably unique, for its admirable advice on the business details connected with the exploitation of inventions from the point of view of the inventor. It gives an excellent summary of patent law and procedure, adequate to the needs of an applicant for a patent who is prepared to employ a patent agent, and this part of the book takes cognizance of the changes introduced by the Patents and Designs Act, 1932. Of considerably greater interest, however, is the astute advice, characterized by much worldly wisdom, given by the author on the commercial aspect of inventing. The limits of the advantages to be gained by mass production, the question of price, advertising, the characteristics of mail-order sales, are some of the topics on which light is shed. The author is something of a psychologist, as when he utters the warning: "Unfortunately the personal friends of inventors are apt to praise any invention out of friendship. . . ." Sir Richard Gregory contributes an interesting foreword in which he discusses some famous patented and unpatented inventions.

(2) This comprises the various patents and designs acts now in force, in consolidated form, together with an alphabetical index to their subject-matter, references being to sections of the consolidated acts; and also a summary, arranged alphabetically on the basis of subject-matter, of the changes introduced by the Patents and Designs Act, 1932.

C. W. H.

Die mitogenetische Strahlung, zugleich zweiter Band der "Probleme der Zellteilung". Von Prof. Dr. Alexander Gurwitsch. Unter Mitwirkung von Lydia Gurwitsch. (Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere, Band 25.) Pp. ix + 384. (Berlin: Julius Springer, 1932.) 33.80 gold marks.

During the past decade, the writings of Gurwitsch and others have made biologists familiar with the conception of mitogenetic rays, that is, radiations emitted from one organic body which stimulate or increase the rate of mitosis in another. The latter biological object is called the detector, and the process of stimulation is known as a mitogenetic effect. Biologists are, however, not yet convinced of the nature or even of the existence of mitogenetic rays.

The present volume explains the methods and instruments used in such experiments and discusses the results, especially in their biological aspects. The book is divided into three parts, dealing respectively with the physics and chemistry of mitogenetic rays, their occurrence in the economy of organisms, and the various biological aspects of the 'mitogenetic effect'. These rays are believed to be produced by bacteria and yeasts as well as the meristems and phloem of higher plants, while other tissues are thought to produce them after wounding or necrobiosis. Experiments also described are supposed to show their production by animal embryos, tissue cultures, blood, ciliated and nerve cells, and numerous experiments with carcinomata are set forth. Since the proof of an induction or mitogenetic effect depends upon the counting of the relative frequency of mitotic figures in the exposed tissue, the difficulty of proving even a single case will be clear.

The real nature of these effects remains to be proved, but anyone interested in the subject will find the experimental work well summarised in this volume. R. R. G.

Medieval Faith and Fable. By the Rev. Canon J. A. MacCulloch. Pp. 345. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1932.) 15*s*. net.

IN "Medieval Faith and Fable" Canon MacCulloch deals with various aspects of religious life and thought in the Middle Ages, regarding them as a student of folk-lore and comparative religion rather than as a theologian. It is generally recognised that the rank and file of the early Christian Church retained many of their pagan beliefs; while popular observance of ecclesiastical feasts and festivals often was allowed to incorporate a considerable element of an earlier ritual. This, however, is not all. The doctrine of the early and medieval Church was itself in many respects an assimilation of conceptions derived from the religions which preceded it.

Canon MacCulloch, bringing his extensive knowledge of elder faiths and folk-lore to bear upon the Middle Ages, here shows to what extent the elements of paganism may be detected as surviving in the medieval view of such matters as fairies, the supernatural mistress or wife, demons, the cults of the Virgin and the saints, the Host, miracles and so forth. One of the most interesting and informative of his chapters deals with medieval heresies, which, when regarded from the point of view taken here, throw much light on the witchcraft belief and persecutions, a subject which the author reserves for future treatment. Canon MacCulloch's knowledge of his subject is encyclopædic. He wastes little time on theory, but gives his readers facts in full measure, not to say running over.

The Atomic and Molecular Forces of Chemical and Physical Interaction in Liquids and Gases, and their Effects. By Prof. R. D. Kleeman. Pp. vii + 133. (London: Taylor and Francis, 1931.) 10*s*. 6*d*. net.

THE difficulties inherent in the task of giving a coherent theory of the fluid state of matter are illustrated in this volume, in which Prof. Kleeman discusses the nature of the law of force between the atoms and molecules of liquids and gases. The physical and chemical properties of fluids must evidently be conditioned by this law, but since the molecules may be in rotation, the law must necessarily be complicated in character. The law can, however, be shown to possess some general functional properties that hold approximately. Prof. Kleeman points out an important property of the force exerted by an atom, namely, that it is measured by the square root of the atomic weight.

The volume contains at least 175 equations, some theoretical, some purely empirical, and some of a hybrid character. How many of the equations in the latter classes will survive critical examination it is difficult to say. Prof. Kleeman has done a useful piece of work in collecting this material but much original investigation, probably on quite new lines, is still required before satisfactory theoretical conclusions can be reached.

The Neural Energy Constant: a Study of the Bases of Consciousness. By John Bostock. Pp. 178. (London: George Allen and Unwin, Ltd., 1931.) 6*s*. net.

DR. BOSTOCK advances a theory that "the nerve energy engaged in consciousness is a constant quantity". It cannot be said that he makes out a good case in support of his theory. His diagrams are like so many of those produced by writers on psychology, probably best understood by himself. There is a number of irritating spelling mistakes and grammatical errors, which should have been eliminated. The statement "fortunately for science this region [the thalamus] is very frequently the site of small hemorrhages" is inaccurate. The thalamic syndrome is distinctly rare. What is described in the text as the *oc*cipital lobe is figured on a diagram as the *de*cipital lobe. The old proverb "when in doubt sleep on it", does not, as the author would have us believe, mean that some mental process full of wisdom takes place during sleep, but simply that on thinking a question over more carefully, and using our judgment more wisely, we may alter our view. There is no need for the author to be troubled at "the intellectual brilliance of many epileptics". They are most certainly the exception; the proportion of clever people among epileptics is distinctly smaller than amongst the normal population.

Effects of Solar Eclipse on Audio Frequency Atmospherics

By EVERETT T. BURTON and EDWARD M. BOARDMAN, Bell Telephone Laboratories, New York City

STUDIES of low-frequency atmospherics have shown marked diurnal variations, the night-time intensity considerably exceeding that of the day.[1] These variations may be attributed to radiation from the sun through its effect on ionisation in the reflecting and absorbing layers of the upper atmosphere. Although it is believed that the major portion of this ionisation is due to sunlight, an appreciable effect may be due to a corpuscular radiation from the sun. A solar eclipse affords an opportunity for comparing light and corpuscular effects, since a difference in velocity of these types of radiation should result in a time separation of the two eclipses at the earth's surface. Prof. S. Chapman[3] has shown that, with an assumed corpuscular velocity of 1,000 miles a second, the corpuscular eclipse precedes the visible one by about two hours. The motion of the moon through a corpuscular radiation results in a trailing shadow. In overtaking the visible shadow of the moon, the earth arrives first at the location of the corpuscular shadow.

Observations of atmospherics during the progress of a solar eclipse should show at least an approximation to night-time conditions, because of the accompanying reduction of radiation intensity. The effects of the two types of radiation on the ionisation in the atmosphere should be sufficiently separated in time to render their effects distinct. To obtain experimental data, apparatus was set up at Conway, New Hampshire, which was in the path of totality of the solar eclipse of August 31, 1932. A vacuum tube amplifier was connected to a vertical loop antenna which consisted of two sections placed at right angles to reduce directional effects. Between the loop and the amplifier were placed networks so designed that all frequencies above the range of interest were eliminated, thus insuring direct reception of audio frequencies without a detection process occurring anywhere in the apparatus. The amplifier output was connected to a thermocouple for amplitude measurement and to a telephone for aural observations. The amplifier gain was essentially uniform from 20 to 3,800 cycles per second. The telephones were of the dynamic type with regular response throughout the voice range. These permitted more accurate observations on static qualities than have been possible with the telephone receivers used heretofore. A calibrated tone circuit, loosely coupled to the amplifier system, was provided for use in determining frequencies of musical atmospherics.

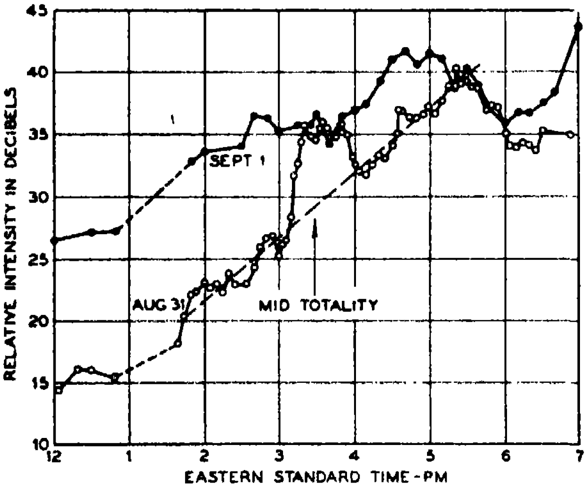

FIG. 1.

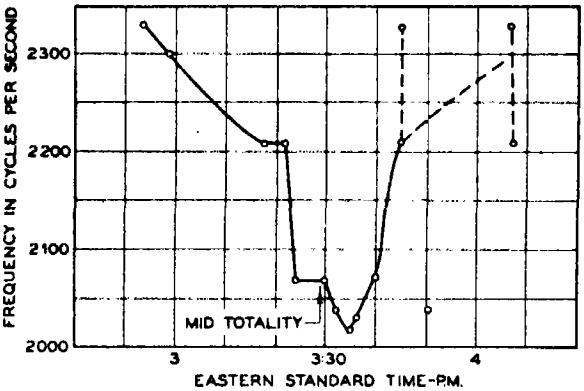

FIG. 2.

Tests at Conway extended from the evening of August 30 until the morning of September 2. Frequent determinations of static amplitude and of static tonal qualities were made. The atmospheric intensity during all of this time was unusually high because of the presence of musical atmospherics of the previously reported type known as 'swish'[1]. While the 'swish' obviously was not related to the eclipse, its presence was unfortunate because of the introduction of irregular variations of intensity. The static intensities for the afternoons of August 31 and September 1 are shown in Fig. 1. While the two curves follow the same general contour, that of the former date shows an abrupt rise shortly before the time of eclipse totality and an abrupt fall after totality. The duration of this period of high intensity is 55 minutes, its mid-time occurring 5 minutes after mid-totality.

Certain types of so-called 'musical atmospherics' normally occur only during twilight or night. One of these, known as the 'tweek', is a short damped oscillation which appears to result from multiple reflections of a static impulse between the earth's surface and a reflecting layer located in the upper atmosphere. 'Tweeks' have never been observed during full daylight, their existence evidently being prevented by absorption in the low-altitude ionisation maintained by sunlight. A phenomenon closely related to the 'tweek' is a weak resonance, observed during evening and morning twilight periods. The resonance has been found to appear near sunset with a frequency of approximately 2,300 cycles per second, reducing gradually to 1,800 cycles per second in approximately two and a half hours, after which it appears to submerge in the night-time static. During the morning twilight period the resonance reappears, rising through the same frequency range and persisting for approximately half an hour. The 'tweeks' suffer similar frequency variations during the twilight periods.

A watch was kept for tonal qualities in the static during the entire day of the eclipse. Shortly after noon, occasional very highly damped oscillations were observed, resembling somewhat the night-time 'tweeks'. Seventeen of these were observed between the hours of 12.35 and 3.50 P.M., a good share of them occurring just previous to one o'clock. While our data are meagre, there is evidence of a maximum in this effect occurring somewhere between two and three quarters and one and a half hours before the time of visible totality. This uncertainty results from the fact that no observations of tone were made between the hours of one and two in the afternoon. As totality approached these highly damped tones were seldom observed, but a weak resonance similar to that of an evening twilight period appeared. The frequency was observed to reduce gradually, reaching its minimum approximately seven minutes after totality. Thereafter it increased rapidly, and disappeared after a short period of rather indefinite frequency. The observations of the resonance tone are shown in Fig. 2.

Our observations of audio-frequency atmospheric intensity indicate an approach to night-time intensity near the period of totality. Data on resonance tone indicate an approximation to evening conditions before and during totality, followed by a condition similar to that of morning. Both the intensity and tonal data show lags of a few minutes in respect to the time of totality. These observations point to sunlight effects on the ionisation of the atmosphere. The occasional occurrence of the highly damped tones long before the time of visible totality may be taken as evidence of the existence of corpuscular radiation, although the data indicate a minor effect. The difference in tonal quality between the early highly damped oscillations and the resonance observed near the time of visible totality indicates the occurrence of some marked change in the atmospheric conducting or reflecting properties, due possibly to difference in penetrating properties of the two types of radiation.

Infestation of Stored Products by Insects

By Prof. J. W. MUNRO, Imperial College of Science and Technology

ALTHOUGH the losses caused to growing crops by insects have long been recognised, the losses caused to crops after harvesting and during storage and transport have been strangely neglected both by the biologist and the industrialist. These losses are none the less of grave importance and take in the main three forms: absolute loss of goods resulting from consumption by the insect, indirect loss resulting from the lower price paid for soiled or infested produce and indirect loss resulting from loss of prestige by the merchant or manufacturer who inadvertently places infested produce on the market. This last form of loss is almost wholly incalculable, but that it is high is evident from the almost extravagant care which our food industries take to prevent any knowledge of infestation from reaching the general public.

In 1926, the Empire Marketing Board appointed a committee—Committee on Stored Products Infestation—to consider this problem and on its recommendation made a grant to the Imperial College, in 1927, for the establishment of a special laboratory for the study of the scientific problems underlying infestation of stored products by insects and fungi.* This laboratory is stationed at Slough, near London. Its work is divisible into three main sections: survey and intelligence work at the London docks; research and experimental work in the laboratory; and commercial scale experimental work on sterilisation of infested produce and warehouses in London and other ports.

The survey or intelligence work is concerned with inspection of such produce as cocoa[1], dried fruits[2] and tobacco[3] on its arrival in London, with a study of the special conditions—economic and climatic—prevailing in the dock warehouses and their relationship to infestation, and with the examination of special 'experimental consignments' of produce shipped from oversea for the purpose of testing methods of preparation, packing and transport and their relationship to insect infestation. With this inspection work there is also regular correspondence and exchange of programmes with departments of agriculture and other institutions in the Dominions and Colonies on problems arising in the work.

A survey of the insects associated with cocoa, dried fruits, spices and tobacco stored in London warehouses showed that upwards of a hundred and forty species of insect are represented, but of these only a few are of primary importance'.[4] These are the phycitid moths of the genera *Ephestia* and *Plodia*, of which the 'flour moth', *Ephestia kühniella*, the 'cocoa moth', *Ephestia elutella*—which is also a serious pest of stored tobacco—and the Indian meal moth, *Plodia interpunctella*—the major pest of dried fruits—are much the most important economically.[5] Of the Coleoptera, the grain weevils, *Sitophilus granaria* and *S. oryzae*; the flour beetle, *Tribolium castaneum*; the 'saw-toothed grain beetle', *Oryzœphilus surinamensis*; the 'biscuit weevil', *Sitodrepa panicea* and *Ptinus* and *Dermestes* species, are the more important or more prevalent.

---

* The term 'stored products' as used here excludes timber, which is dealt with by the Forest Products Research Laboratory of the Department of Scientific and Industrial Research.

The characteristics of the stored products fauna have been discussed by van Emden and by Richards[6]. The chief of these appear to be low water requirements and lack of specialised oviposition response.

The main results of the survey work so far have been to show that in nearly all—if not all—instances, infestation begins in the exporting country and that it is aggravated by storage in Great Britain. The work has also served to show that close co-operation of the producers, merchants, wharfingers and manufacturers is essential if freedom from infestation problems is to be attained. In the dried fruit industry it has been clearly shown that due precautions taken in the packing sheds of the exporting country will ensure lower insect infestation of fruit on its arrival in Great Britain.

The laboratory research and experimental investigations in progress comprise entomological, mycological and chemical work. In the entomological branch, the problems studied are concerned mainly with the rearing of very large numbers of insects for experimental work on such lethal agents as heat, cold and fumigant gases, and with various problems relating to the respiration of insects in different stages of development. Of special interest is a study of the factors governing the fertility and rates of increase of the phycitid moths. A description of the pairing habits of these moths has been published[7] and an account of sterility produced in the males by rearing at temperatures above the optimum for development awaits publication.

In the mycological branch of the laboratory, special attention has been given to copra[8] and to cocoa[9] and an extensive programme of work on the taxonomy and physiology of the mould-causing fungi of the genera *Penicillium* and *Aspergillus* has been begun.

In the chemical section of the laboratory, research and experimental work on the relative toxicity of various fumigants to insects and on the partial vapour pressures of fumigant vapours and gases generally used in admixture, for example, ethylene dichloride and trichlorethylene has been carried out and awaits publication. Especially important is a study of the methods of measuring the concentration of gases during fumigation[10] and the devising of special apparatus for this purpose. Work on the methods of determination of the fumigants ethylene oxide[11] and hydrocyanic acid, both in the air spaces and in the products fumigated has made good progress.

The commercial scale experimental work undertaken by the laboratory has been made possible by the generous facilities placed at its disposal by a number of interested firms, among whom Messrs. Weber, Smith and Hoare, wharfingers, and the London agency of the Australian Dried Fruits Board deserve special mention. While laboratory experimental work has very high value, it is almost impossible to simulate in the laboratory the extraordinarily varied conditions affecting sterilisation on a commercial scale. Where cold lethal temperatures are employed, the chambers used in commercial cold storage have been found satisfactory and this method is especially applicable to the sterilisation of almonds and nuts and tobacco. Where, however, fumigation is employed, the problems are many and difficult, for some of these warehouses have a capacity of 250,000 cubic feet and house many hundreds of tons of produce.

In fumigation of ships, warehouses, mills and produce as practised commercially, it was found that no serious attempts are made to determine the behaviour of the gases used during the actual process of fumigation. Moreover, such concentrations of fumigants as are recommended or employed in practice are based on experimental work in which the kind and extent of living insect material used are quite inadequate. Five, ten or, in rarer cases, thirty insects of unknown antecedents appear to be considered ample for this work. In our experience, such numbers are far too small and until we were employing in our commercial work from 2,000 to 4,000 insects or insect eggs reared or produced under known conditions, we were not satisfied with our results. A study of the behaviour of gases during fumigation showed that temperature effects are not allowed for at all, the very high absorption of fumigants by the products themselves and by such things as walls and 'dunnage'—boards used as a base for piles of fruit boxes, sacks, etc.—is altogether underestimated and quite inadequate measures are taken to ensure proper diffusion and distribution of the gas. It is probable that the most important direct contribution our laboratory has so far made to the 'control' of insect infestation is in directing attention to these defects and providing means of overcoming them. The methods used in measuring concentrations of gases in fumigation have already been described elsewhere[10]; meanwhile, two very important advances in the technique of fumigation have followed. On one hand a higher percentage of destruction of the insects has been secured, and on the other, a more uniform distribution of the gas has been attained, even in very large warehouses in cold weather. This work is, of course, still in the experimental stage, but there is every reason to hope that soon we may find commercial fumigation placed on a scientific basis, with the result that it will be safer for those engaged in it, more efficient against insects and less injurious to the product treated.

Efficient fumigation, however, is not the final aim of our work, which is the reduction of infestation at its source, and while physical and chemical measures may prove palliative, it cannot be too strongly emphasised that the ultimate reduction of the losses caused by insect infestation of stored produce depends on the acquisition of a fuller knowledge of the insects concerned than we possess at present. Subjects on which promising research work is being conducted as time and funds allow are the temperature and humidity conditions—both in the atmosphere and in the products—which are most favourable to various insects, and the relationship of the mould-causing fungi to the insects' food supply. For the present, this research work may appear of less practical importance than the improvement of remedial measures, but as these measures lessen the incidence and extent of infestation and more attention is given to preventive measures, the value of the more purely biological research work will be more appreciated. Already in some of the industries affected by insect infestation of their raw materials, the need is felt for fuller knowledge of the influence of ventilation and air conditioning and of different kinds and intensity of lighting on the prevalence of warehouse insects.

Museums of Canada*

THE two volumes referred to below may be regarded as a continuation, first, of the report on the public museums of the British Isles drawn up for the Carnegie United Kingdom Trust by Sir Henry Miers in 1928, secondly, of the new edition of the "Directory of Museums", originally published by the Museums Association in 1911, of which vol. 1, covering Great Britain and Ireland, appeared in October 1930. This continuation, which will eventually deal with all the public museums of the Empire, has the aid of the Carnegie Corporation of New York. The report, by Sir Henry Miers and Mr. S. F. Markham, is confined to the museums of Canada, but the "Directory" comprises also the other museums on or adjoining the American continent and is on the same clear and practical lines as the first volume. We base our further remarks on the Canadian report.

The authors include any building that houses objects of art, history, science, or industry to which the public has even limited access. Of such museums they reckon 125, and nearly all have been inspected by one or the other author. The *museum service of Canada differs from that of* Great Britain in the relatively smaller number of museums maintained by public funds. While 28 are administered by the Dominion Government or provincial governments and only seven by a city or county, *there are 32 maintained by a* society, 53 by educational establishments, and *5 owned by industrial firms*. The classification is not exact as the administration is often shared between public and private bodies. Of the society museums, at least half are historical, and these are mostly in Ontario; of the educational museums *22 belong to Roman Catholic institutions in* Quebec. Fifteen, of varied character, are classed as art museums and range through eleven towns from Vancouver to Halifax.

While a few of these museums, both large and small, are on a high level, it is not surprising that many are open to the criticisms that not so long ago were passed upon most of the museums in Great Britain. To the defects of building with which we are familiar, especially when collections are shown in a house not intended for that purpose, is frequently added that danger from fire natural in a country where wood is used so largely. Save in the half-dozen leading museums, cases are not dust-proof and often not moth-proof, or even lacking altogether. While some exhibits are commended, there is generally a want of adequate labelling and in this respect the art galleries, as elsewhere, are sadly to seek. Still worse is an absence of plan, so that objects which might teach a lesson remain mere curios; here the special museums have an advantage over those covering a wider field. Underlying all these defects is, as usual, the lack of a proper staff. It is almost incredible that "only in a score of museums . . . is there a competent full-time curator, and that in only eight of the score are there adequately qualified museum assistants". Not only this, but also the best of the curators are attracted to the United States by the higher pay and status.

---

* A Report on the Museums of Canada, by Sir Henry A. Miers and S. F. Markham, to the Carnegie Corporation of New York, to which is appended a Directory of the Museums of Canada and other parts of the British Empire on the American Continent. Pp. vi + 63 + 2 plates. Directory of Museums and Art Galleries in Canada, Newfoundland, Bermuda, the British West Indies, British Guiana and the Falkland Islands. Compiled by Sir Henry A. Miers and S. F. Markham. Pp. 92, 5s., with Report. (London: The Museums Association, 1932.)

It is plain that Canada, in spite of its fine schools, universities, and public libraries, has not yet realised the educational value of museums, a value that has only recently been admitted in Great Britain. There are indeed some school museums, but most of them are neglected and bear no more relation to the curriculum than with us. In nearly half the museums, some instruction is given to school classes, but there is no true co-operation with the educational authorities. Thirty museums lend specimens to schools and a few are really active in this direction. These are hopeful signs and one can scarcely doubt that the lead of the United States will before long be followed.

Looking at the state of affairs still more broadly, the authors find an absence of co-operation. Were this need supplied, the few really good museums could do much to raise the general level. Towards future progress the criticisms and suggestions of this most valuable report cannot fail to be an inspiration and a guide.

Obituary

DR. ERNEST CLARKE

ERNEST CLARKE was a well-known London eye-specialist. Born in Hampstead on July 21, 1857, he died on November 22, 1932. His career is well described in the medical journals of December 3. Educated at University College School, he joined St. Bartholomew's Hospital Medical School in 1876. He began his career in 1880, as a general practitioner at Blackheath but soon turned to ophthalmic work and moved to Chandos Street, W. He was very successful, through making the correction of small errors of refraction his special care.

A linguist, a traveller, a musician specially devoted to the organ, an enthusiastic collector, a keen freemason, gifted with a cultivated mind, both artistic and scientific, Clarke was a most engaging personality. Happy in his success, he enjoyed good health until recent years, when he suffered much as a result of some infection, I believe, but was stoically cheerful and active to the last. A member of the Royal Institution since 1896, he was a constant attendant and one of its most valued helpers.

I knew him in his student days, as an alert member of my First M.B., University of London tutorial class, at St. Bartholomew's Hospital. No small part of my organic chemistry (1874) was ingested into him; how much he eventually digested I will not say. Among medical men he has always appealed to me by the clearness of his scientific outlook and entire absence of pose. It is interesting to compare training such as he had with the present. Except anatomy, no preliminary subject was then taught practically. A beginning had been made, in physiology, at University College and we know that Michael Foster introduced the subject at Cambridge in 1876; yet Lauder Brunton and I, already in 1868-69, had attended a wonderful lecture course by Ludwig, in Leipzig, which was minutely experimental from beginning to end and, as a consequence, unforgettable. Idealists have made such teaching impossible here to-day.

H. E. A.

DR. J. J. CARTY

DR. J. J. CARTY, for many years connected with the Bell Telephone System in America, died on December 27 at the age of seventy-one. He had retired from active service in 1930. Carty played a great part in the development of electrical communication, and was probably as instrumental as any one man in the creation of the present-day American telephone system, which involves some twenty million stations and eighty million miles of wires.

Carty was appointed chief engineer of the New York Telephone Company at a time when the problem of placing exchange wires underground was pressing for a solution, and he guided the successful development of the lead-covered paper-insulated cable. Later he became chief engineer of the American Telephone and Telegraph Company, and in this capacity he carried through to successful conclusion the building of the first transcontinental telephone lines in 1914–15, including the adaptation of the vacuum tube amplifier to the telephone repeater. Later in the same year he was able to announce the bridging of the Atlantic Ocean by radio telephone. He was also instrumental in the development of lead-covered cables for long distance telephony, the first undertaking of this kind being the Boston-Washington toll cable of large gauge wire which was placed in operation in 1913. This was followed by the New York–Chicago toll cable, the first to use small gauge wire, in 1921.

Dr. Carty was a member of the National Research Council of America, and a member of council of the National Academy of Sciences of the United States. In 1915 he was elected president of the American Institute of Electrical Engineers. In 1903 he was awarded the Longstreth medal and, in 1916, the Franklin medal of the Franklin Institute; and in 1918, the Edison medal of the American Institute of Electrical Engineers.

To those who worked for him, Dr. Carty will be as much remembered for his inspiring leadership as for his deep knowledge of electrical communication.

PROF. A. M. STALKER

ALEXANDER MITCHELL STALKER, who died in Dundee on December 23, was born in Leven in 1853. After an arts course from which he graduated with first-class honours in mental philosophy, he entered on the study of medicine and after graduating at Edinburgh he studied also at Leipzig.

Ultimately he started practice in Dundee, where he was soon appointed physician to the Royal Infirmary. Distinguished not only by his clinical skill but also by his wide philosophic outlook, he became a leader in a group of younger men who were raising medicine in Dundee to the academic standard that fitted it, when the time was ripe, to furnish the Medical School of the University of St. Andrews.

In 1898 Stalker was with universal approval appointed the first professor of medicine in the new School and grasped whole-heartedly the opportunities afforded of service to medical education in the training of his students. His aim throughout was to lay clearly the main lines on which medical knowledge could be interpreted and applied. In this he was singularly successful, while at the same time he imbued his pupils with an enthusiastic curiosity that encouraged them to track to its place anything which they might encounter outside the range of their previous experience.

Prof. Stalker was endowed with an unusual memory and, widely read, not only in philosophy but also in general history and literature, he was able by accurate reference to keep medicine in touch with the general body of knowledge. Though a good writer and a fine lecturer, his publications were limited to occasional papers, in the interests of his routine duties as physician and teacher. In 1924, when he retired, the University in recognition of his services conferred on him the degree of LL.D.

MR. G. R. CARLINE

GEORGE REGINALD CARLINE, who died in London on December 24 at the age of forty-seven years, succeeded the late H. Ling Roth as keeper of the Bankfield Museum, Halifax, in 1924. He continued the work of his predecessor in adding to the collections of the Museum illustrating the development of the primitive loom and weaving technique. Formerly he had been assistant curator to the Wellcome Historical Medical Museum, London, and afterwards at the Pitt-Rivers Museum, Oxford. In 1929 he accompanied the British Association to South Africa, contributing to the proceedings of Section H (Anthropology) a paper on the handloom in Africa, and afterwards spending some time in observation among the Mambwe tribe of Northern Rhodesia. He had excavated with Sir Flinders Petrie in the Fayum in 1925 and was closely associated with the work of the Folk-Lore Society and the Royal Anthropological Institute, and was a contributor to their journals.

WE regret to announce the following deaths:

Mr. Cecil Fowler Beadles, curator of the Pathological Department of the Museum of the Royal College of Surgeons, on January 3, aged sixty-six years.

Prof. Robert Donaldson, Sir William Dunn professor of pathology in the University of London, on January 3, aged fifty-five years.

Dr. Malcolm Evan MacGregor, director of the Wellcome Entomological Field Laboratory, of the Wellcome Research Institution, who has done much work in connexion with malaria, on January 12, aged forty-three years.

Mr. J. L. S. Hatton, Vice-Chancellor of the University of London, and first principal of East London College, on January 13, aged sixty-seven years.

Sir Robert Jones, K.B.E., president of the Association of Surgeons of Great Britain and, in 1921–25, president of the British Orthopædic Association, on January 14, aged seventy-four years.

Mr. Basil H. Soulsby, formerly librarian of the British Museum (Natural History), on January 14, aged sixty-eight years.

Prof. C. M. Thompson, emeritus professor of chemistry in the University College of South Wales and Monmouthshire, on January 4, aged seventy-seven years.

News and Views

Sir Edward Sharpey-Schafer, F.R.S.

SIR EDWARD SHARPEY-SCHAFER, who will retire from the chair of physiology in the University of Edinburgh at the end of next September, went to Edinburgh in 1899 from the Jodrell chair of physiology in University College, London. He has administered an important department and lectured to large classes of medical students, but he has also had abundant energy left to devote to his numerous investigations, which have extended over a wide field including general histology, the endocrine organs, the nervous system, the pulmonary circulation and artificial respiration. His published books include his masterly work on the endocrine organs and his well-known "Essentials of Histology", which has passed through seven editions since its author went to Edinburgh. The feature of Sir Edward's work in the University of Edinburgh has been his emphasis on, and his encouragement of, research. In his eighty-third year, he is still active and acute in mind, and as keen and assiduous as ever in the prosecution of research. His retirement from the chair will remove one of the best-known figures in the University Medical School and the senior member of the Faculty of Medicine.

APPRECIATIVE reference should also be made to Sir Edward's services, outside his University duties, for example, as founder in 1908 of the *Quarterly Journal of Experimental Physiology*, which he has edited throughout its existence, and to his continued interest in the Physiological Society, of which he is now the only remaining founder member. Of his more general services to science may be noted his work as general secretary of the British Association (1895–1900) and as president of the Dundee meeting in 1912, and his presidency of the Royal Society of Edinburgh since 1929. Sir Edward was elected a fellow of the Royal Society of London so long ago as 1878. He received a Royal medal in 1902 "for his researches into the functions and minute structure of the central nervous system, especially with regard to the motor and sensory functions of the cortex of the brain", while in 1924 he was awarded the Society's supreme honour, the Copley medal. In making the presentation of the Copley medal, Sir Charles Sherrington described Sir Edward's fundamental work on the adrenal and pituitary glands as opening up a modern chapter of physiological knowledge with important consequences for medical studies and treatment.

China and American Scientific Expeditions

BY favour of Dr. Henry Fairfield Osborn, president of the American Museum of Natural History, we have received a copy of his reply to the communication from the Chinese National Committee for the Preservation of Antiquities in reference to the Museum's expedition to Inner Mongolia and the rupture in the relations for scientific co-operation between the Museum and Chinese scientific men (see NATURE, 130, 803, Nov. 26, 1932). In his reply Dr. Osborn points out that the American expedition has worked under an agreement made in 1921 whereby, provided its operations were confined to regions where the Geological Survey of China could not work, it was to be unhampered in Mongolia; but, he maintains, the Geological Survey has not adhered to its part of the bargain. In 1928 the expedition's collections were detained at Kalgan for six weeks, without legal or moral right; and the expedition was charged with possessing only "hunting permits", although the permits were the same as in preceding years and the character of the work on which the expedition was engaged was universally known. In 1929 the expedition was not allowed to proceed in the field as the demands made by the Chinese commission were "exorbitant and without international precedent".

IN the Chinese communication, it will be remembered, stress was laid on the fact that Dr. Andrews had assured the commission that the expedition of 1930 was to be the last of the series, but that in 1931 he had applied for a permit for further work in Mongolia. Here Dr. Osborn states that further work had been made necessary by the discoveries of the expedition in 1930 and the negotiations were opened at his request; yet Dr. Andrews was not even given an interview. He then deals with the termination of the Museum's work in China and the transfer of its activities to Manchukuo, a decision which was reached after mature deliberation. Further, he points out, the closure of the Museum headquarters at Peking by Dr. Andrews was not unauthorised, as has been suggested, but was effected with full authority as the officer of the Museum in charge of exploration and under direction. In expressing the regret of the American Museum that the friendly relations between Chinese scientific men and the American Museum, which existed until 1928, should be thus severed, Dr. Osborne feels that it is through no fault on the side of the Museum. Dr. Andrews insisted on the privilege of completing the work in Mongolia under the agreement of 1921. This made him unpopular with the commission, but no other course was open to him. Dr. Osborn concludes, "It is difficult to see how it would be profitable for this Museum to conduct field work under any other conditions."

Technocracy

RECENTLY in the United States the new economic doctrine of 'Technocracy' has aroused much attention and provoked much discussion. This movement has been sponsored by a number of engineers and scientific workers, and according to an article in the *Times* on January 5, its underlying thesis is that the tremendous technological advance made in industrial processes during the past century and particularly during the past twenty-five years has rendered all existing social and economic mechanism obsolete and futile. 'Technocracy' claims that scientific discovery and modern engineering skill have now armed mankind with powers that would ensure leisure and plenty for all if only they were properly employed. It asserts that the basic factor in social life is the amount of energy available for productive purposes and that no solution is possible so long as the present price system is retained. Energy, according to the exponents of 'technocracy', is the real measure of human labour and human wealth and therefore real prosperity will only be obtained when individualism is discarded and an entirely new system of distribution based on 'energy certificates' instituted. At present, however, as the *Times* article states, the highly technical language in which most of its statements are shrouded make certain aspects of the theory obscure while others could be refuted by any economist without difficulty. The lines of research and the deductions drawn from the assembled facts are obviously the work of engineers thinking in terms of mechanical production and ignoring all considerations of human psychology.

British Industries Fair

THE 1933 British Industries Fair, which opens on February 20 and continues until March 3, will be held, as last year, at Olympia and the White City in London, and at Castle Bromwich in Birmingham. It still goes on expanding. This year the Fair will be bigger, the exhibits more varied and the exhibitors more numerous than ever before. What is perhaps of more importance is that all indications up to the present point to the probability of a great increase in the number of buyers who will attend. For example, the acceptances by overseas buyers of invitations issued by the Department of Overseas

Trade, which organises the Fair, are already 30 per cent more numerous than those received last year. Sixteen European countries, as compared with only five countries last year, are providing special travelling facilities at reduced rates to encourage their buyers to attend the Fair. Altogether some fifty-six different countries and territories will be thus represented. The Fair may be expected to show in what ways and to what extent British manufacturers have availed themselves of the competitive advantages obtained through Britain's abandonment of the gold standard and as a result of the Ottawa Conference. We hope to deal with scientific aspects of the Fair at a later date, but it is satisfactory to note now that scientific and optical instrument makers will be well represented.

Association of British Zoologists

DR. J. GRAY was in the chair as president at the annual meeting of the Association of British Zoologists, which was held in the rooms of the Zoological Society on Saturday, January 7. The morning session was given to discussion of several motions concerning the teaching of biology. It was moved by Prof. E. W. MacBride that vacation revision courses at the universities are highly desirable for teachers of science in schools. This motion was supported by several speakers, but the danger that such courses should be considered sufficient substitute for previous training in the sciences which the teacher was expected to teach was emphasised by Prof. W. Garstang and Prof. Graham Cannon. Mr. H. R. Hewer gave an account of the proceedings of the recent National Conference on the Place of Biology in Education. It was suggested by Prof. Douglas Laurie and Prof. J. S. Huxley that in elementary education a general scientific course is required rather than one in which the scientific subjects are separately organised, but that in such a general course biology must have a leading part. A discussion on the best way of influencing the teaching of biology in schools was introduced by Prof. Graham Cannon. He suggested that this could best be done through the examination boards of the country and in this was supported by Dr. Philippa Esdaile. The president suggested that many of the present difficulties are due to the absence of any body with the function of correlating school and university teaching.

DR. GRAY spoke on "The Importance of Zoological Advice to the State". He said that although the supply of biologists has greatly increased in recent years, there is still great difficulty in persuading good students to undertake work in Government employ. He considers this is partly due to the absence of liaison between the teachers at the universities and those who would later employ the biologists. Some body which could undertake the maintenance of this liaison would be useful. In the afternoon, Mr. W. B. Alexander spoke on the conduct of British ornithological surveys and mentioned the proposed founding of an Institute of Ornithology to deal with such subjects. Several speakers joined in the discussion of a motion introduced by Prof. F. Balfour Browne concerning the confusion in systematic zoology which results at present from the frequent change of zoological names necessitated by the strict application of the law of priority to them and from the small number of *nomina conservanda* which the International Commission on Nomenclature is able to set up. It was agreed by 23 votes to 3 "that British zoologists should at once set about making a list of proposed *nomina conservanda*, and that to this end a committee of zoologists should be constituted".

Earthquake in the North of England

AN earthquake, rather strong for England, occurred at about 8.30 A.M. on January 14. It has been suggested that it was one of the numerous earth-shakes felt along the Irwell Valley fault near Manchester rather than a genuine earthquake. It differed, however, both in intensity and disturbed area from these local shocks, the strongest of which so far known (that of November 25, 1905) only attained the degree 7 (Rossi-Forel scale) and disturbed an area of 144 square miles. So far as we can judge from the early reports, the earthquake of January 14 was strongest in and near Wensleydale, so that it may have been connected with the well-known Craven fault. At Hawes and the neighbouring village of Bainbridge, a few field-walls and chimney-pots were thrown down. The shock was felt over a wide area, from the Point of Ayre lighthouse in the Isle of Man to Whitby and Bridlington, as well as at Manchester, Altrincham, etc. The disturbed area must thus contain about 25,000 square miles. The earthquake was recorded at Stonyhurst and West Bromwich, but not at Kew Observatory.

Recent Chinese Earthquake

A VERY severe earthquake occurred in north-west China on December 25. From records at nine widely distributed observatories, the U.S. Coast and Geodetic Survey places the epicentre in lat. 40° N., long. 98° E. (Wire Report of Science Service, Washington, D.C., Dec. 27.) This point lies between the towns of Su-chow and An-hsi-chow, near the edge of the Gobi desert, about 300 miles north-west of the epicentre of the great earthquake of 1927. The earthquake must have been very destructive, but, owing to the isolation of the district, weeks may elapse before accounts arrive from the central area.

The Institute for Advanced Study

THE Institute for Advanced Study in the United States was founded in 1930 by a grant of 5,000,000 dollars from Louis Bamberger and Mrs. Felix Fuld. Dr. Abraham Flexner, director of the Institute, has announced that it will be opened in the autumn of 1933, and will be housed temporarily in Fine Hall, the graduate mathematics building at Princeton University. Prof. Albert Einstein has accepted a life appointment as head of the Institute's School of Mathematics. Prof. Einstein will make his home at Princeton; he will be in residence at the

Institute annually from October 1 until April 15, beginning next autumn, and will make a yearly visit to Germany. He will devote all his time to the Institute, and his trips abroad will be vacation periods at his summer home outside Berlin. The following appointments have also been made: Dr. Walter Mayer, of Berlin, Prof. Einstein's assistant, to be associate in mathematics; Prof. Oswald Veblen, generally recognised as one of the leading American mathematicians, and at present professor of mathematics in Princeton University, to be professor; Dr. J. L. Vanderslice, a young Princeton graduate student who has been Prof. Veblen's assistant at Princeton, to be his assistant at the Institute.

THE Institute will be unique among American institutions of higher education, being based upon ideas designed to make it 'a scholar's paradise'. It will concentrate its aim exclusively upon quality in the selection of its teachers and students, and in the nature of its work in scholarship and research. It is hoped that the Institute will accomplish certain definite things in setting a new trend in higher education in America. The salaries paid to its staff and faculty will be on such a scale as to show how much greater results may be obtained when teachers are freed from the necessity of seeking additional remuneration outside the university, and the entire staff of professors and assistants will be on the full-time basis of employment. More emphasis will be laid upon the individual among university graduates, and it is expected to attract students of an independent turn of mind. In order to further this aim of individualism, the Institute will remain entirely separate from any conventional university or college conception. Dr. Flexner makes it clear that while the Institute will occupy temporary space in a Princeton building, it will not be a part of Princeton University. The Institute will consist of a series of schools the first of which will be the School of Mathematics; the second, it is hoped, will be a School of Economics and History. It will be exclusively post-graduate.

'Ethnogenics'

CAPT. GEORGE PITT-RIVERS has published in amplified form (*Human Biology*, vol. 4, No. 2) an address originally given before the Section H (Anthropology) of the British Association, in which he coins the term 'ethnogenics' for "the study of those forces, amenable to social control, which may influence the fertility and survival rate of variations of type in a population". He discusses the early history of anthropology, its long period of infancy as a science, and the reasons why anthropologists continue to regard it as an infant science. This appears to arise from a failure to agree about the scope of anthropology or as to how its subject matter should be classified. The view is emphasised that the progress of anthropology depends on a re-synthesis of its various branches, biological and cultural, including eugenics, genetics, demography, population questions and psychology. The conceptions of race, population and culture as the tripartite aspects of man in time, conditioning and being conditioned by the environment—all are included in the implications of race-population change or ethnogenics. The need for studies of racial, social and economic disintegration among civilised as well as primitive peoples is emphasised.

Expedition to Northern Iraq

THE departure is announced of a joint expedition of the British Museum and the British School of Archæology in Iraq (Gertrude Bell memorial) to conduct excavations at Arpachiyah, on the upper Tigris, four miles east of Nineveh. The expedition will be under the direction of Mr. M. E. L. Mallowan, who was with Dr. R. Campbell-Thompson at Nineveh last year. The choice of site has been determined by the fact that it is the only known prehistoric site in northern Mesopotamia. The investigation on which Mr. Mallowan was engaged last year on the neighbouring site of Nineveh reached virgin soil at a depth of 92 ft., of which 72 ft. was prehistoric material, and revealed evidence of five stages of culture, ranging in date from about 3000 B.C. (Stage 5) to about 5000 B.C., polychrome pottery being found in Stage 2, which in its earliest form showed affinities with Samarra ware. At Arpachiyah evidence of culture comparable with that from the archaic levels at Ur, Kish and Erech has been found and the surface finds are similar to material from the bottom of a pit at Nineveh. It may, therefore, be expected with some confidence that excavation at Arpachiyah will yield evidence which will much enlarge knowledge of the very early periods of civilisation in northern Mesopotamia.

Spike Disease in Indian Sandal

AN editorial article in the September number of the *Indian Forester* (vol. 43) deals with progress in forestry research. The writer commences by directing attention to the report of the seventh Spike Conference (reproduced in this number). It is more than thirty years since the first attempts to study the spike disease of sandal were made. Sandal is one of the major forest products throughout southern India, and the value of the trade in this precious timber amounts to 30–40 lakhs of rupees annually, apart from the market value of the sandalwood oil. Most of the sandal-bearing forests are affected by the spike disease, the presence of which reduces the sandal output by about half, and in many places has killed out valuable crops. So far, in spite of the close study made, no cure has been found and the issue is complicated owing to the sandal being itself a parasite and unable to flourish without some other tree species as a host. The various governments affected have combined in the research work which is now being conducted on an intensive scale. Spike disease of sandal is but one out of many problems which await the investigator in Indian forest research. The Government forest estate alone covers an area of 160,000,000 acres; the forest area in the Indian States covers 45,000,000 acres; whilst in addition there is an even larger area of private and village forest lands. Probably about half of the 160 million acres of forests under the control of the Indian Forest Department are commercially productive, the other half being conserved for the use of right holders or serving as purely 'protection forests'. In spite of this, the revenue has risen from 70 lakhs (a surplus of 17 lakhs) in 1870 to 6 crores of rupees (surplus 2½ crores) in 1930. Research has, so far, cost Rs. 3·6 per square mile, as against a surplus of Rs. 105 per square mile.

Agricultural Research in Great Britain

The report on the agricultural research work carried out in Great Britain with the aid of State funds during the year 1930–31 has now been published by the Ministry of Agriculture (London: H.M. Stationery Office, 1932). The volume, which aims at presenting in convenient form the progress made at the various research institutes and other centres in Great Britain, is planned on the same lines as that issued in the preceding year, with the additional feature of a list, at the end of each report, of papers published during the year by the institute or research centre in question. References to the papers will be found in the text, and the lists will take the place of the annual volumes of "Abstracts of Papers on Agricultural Research in the United Kingdom", the publication of which has been discontinued. It is evident that many important results have been obtained in a number of branches of the subject, but the investigations are too numerous and cover too wide a field to allow of even brief reference being made to them individually. Those desiring further information regarding any subject dealt with in the reports are invited to communicate with the director or other persons concerned, for which purpose a list of names and addresses of directors of research institutes and persons in charge of investigations at other centres is given in the appendix.

High Pressure Boilers

A paper on high pressure boilers read to the Institution of Electrical Engineers on December 15 by C. H. Davy and C. H. Sparks gives an interesting account of the development of the use of very high pressure steam in modern boilers. Prior to 1918, no plants had been placed in commercial service with steam pressures exceeding 350 lb. per sq. in. In 1923 the Edison Company at Boston ordered the first boiler unit suitable for a pressure of 1,200 lb. per sq. in. The construction of this boiler was made possible by the use of the first seamless forged steel boiler drum. Recent developments of X-ray technology have given the manufacturer of welded drums the long sought non-destructive test. A definite proof of the satisfactory condition of a metallic arc fusion weld can now be given by radiographic examination. By means of scientifically controlled welding, drums can be produced which are more suitable for working conditions than the riveted structures used in the past. The drums forming part of the 1,400 lb. per sq. in. pressure sectional boilers at present being installed at the Dagenham plant of the Ford Motor Co. are 45 ft. long, 48 in. in internal diameter, 5 in. thick and weigh 62 tons. The production of such forgings reflects great credit on the forge-masters. Whilst the trend of invention has been definitely towards higher final steam temperatures, it is probable that these will be limited, at least for the present, to below 850° F. This is due to the fact that the cost of 'special' steels is still very high and so it is not economical to use them. The Philip Carey Works at Ohio, which started last year, use a steam pressure of 1,800 lb. per sq. in. The demand for high pressures and consequently high temperatures continues for power stations but super-pressure boilers are mainly used in industrial work.

Map of East Greenland

A new map on a scale of 1 : 200,000 of the coastlands of East Greenland between Sofia Sound in about lat. 73° N. and Young Sound in about lat. 74° 10′ N. based on surveys by Norwegian expeditions in 1929 and 1931 has been published by Norges Svalbard og Ishavs-Undersökelser. This includes the coasts to the north and south of the Norwegian meteorological observatory at Myggbukta in Mackenzie Bay in lat. 73° 29′ N., long. 21° 34′ W. This coast was first sighted by Hudson in 1607 and has since been explored by various expeditions, including those of Clavering in 1823, Nathorst in 1899 and in the north by Wordie in 1926. While much detail is still omitted, the new chart shows many advances on previous ones.

Anti-Veterinary Propaganda

In the autumn issue of *The Fight Against Disease*, the quarterly journal of the Research Defence Society, attention is directed to the attacks which anti-vivisectionists, and notably the National Anti-vivisection Society, have made and persist in making on the Royal Veterinary College and on any other organisation which helps to further veterinary science, with attempts to divert funds from the Tail Wagger's Club. In regard to the last named, the governors of the College have stated that no part of the funds or income arising therefrom is applied in vivisectional experiments. Prof. F. T. G. Hobday, whose name appeared in the New Year honours list as the recipient of a knighthood, the principal of the Royal Veterinary College, in the recent Alexander Pedler Lecture of the British Science Guild (British Science Guild, 6 John Street, London, W.C.2. 1*s*.), also emphasises the humane side of veterinary practice for the animals themselves, and declares our deep and heavy responsibility in ensuring that we act humanely towards the animals in our charge.

Collecting and Preserving Worms

A useful guide for the collector, No. 12 of the British Museum (Natural History) series of "Instructions for Collectors", deals with the various groups of worms. Short descriptions and illustrations are given of the characteristic features of the main groups, with hints as to the places where they are likely to be found. But the most serviceable features are the precise instructions for collecting worms, free and parasitic, and for anæsthetising and preserving them. The pamphlet, of 22 pages, is sold at the British Museum (Natural History) at *6d.*

Ultra-Violet Light at British Health Resorts

FIGURES of the amount of ultra-violet light enjoyed by thirty-two British health resorts during the summer months, July, August, and September, are given in *Sunlight* (vol. 2, No. 7, p. 209). St. Ives heads the list with a daily average of 6·6 'units', and none had less than 1·3 units. Half a unit is sufficient to cause perceptible sunburn.

Spring Lectures at the Royal Institution

THE session of public afternoon lectures at the Royal Institution was opened by Prof. J. C. McLennan, who is giving an experimental course on the work on "Low Temperatures and Low Temperature Phenomena" with which he and the University of Toronto have been specially identified. A course on "Recent Advances in Genetics" is to be given by Prof. J. B. S. Haldane, who has recently returned from a visit to the laboratories at the University of California and elsewhere in the United States. Later courses are by Sir William Bragg, who will review the progress in the past twenty years of the science of crystal analysis by X-rays; and Mr. A. R. Hinks, secretary of the Royal Geographical Society, on "Geography in the Public Service". Mr. Hinks will speak on the new one inch Ordnance Survey map, and the delimitation of national boundaries. Lord Rutherford will give a Saturday course on the "Detection and Production of Swift Particles". The course will be experimental, and as a part of his subject Lord Rutherford will describe the recent progress at the Cavendish Laboratory by Chadwick, Cockroft and Walton and others. Sir James Jeans will give a course on "Modern Astronomy". The new Fullerian professor of physiology at the Royal Institution, Prof. G. Elliot Smith, will give a course on the "Evolution of the Mind". The session will conclude with a display of films, entitled "Developments in Cinematography". Instructional films, colour films, and films in relation to aeronautical research will be shown.

Announcements

AT a meeting of the Harrison Memorial Prize Selection Committee on January 13, the Harrison prize for 1932 was awarded to Dr. H. J. Emeléus, of the Imperial College of Science, London.

THE Gold Medal of the Royal Astronomical Society has been awarded this year to Dr. V. M. Slipher, director of the Lowell Observatory, for his spectroscopic researches on planets, stars and nebulæ. Dr. Slipher has been invited to deliver the George Darwin Lecture for 1933. At the annual general meeting of the Society on February 10, the president, Dr. H. Knox-Shaw, will deliver an address on "The Distances and Motions of the Extra-Galactic Nebulæ".

THE following have been appointed to the Safety in Mines Research Board: Dr. C. V. Drysdale, director of Scientific Research at the Admiralty, Mr. F. Edmond, chief mining agent to the Wigan Coal Corporation, Ltd., and Major H. M. Hudspeth, chief mining engineer to the Board. The appointment of Prof. J. F. Thorpe would normally have ended on December 31 last, but Prof. Thorpe has accepted a special extension of his term of service for a period of two years. Prof. C. H. Lees, whose appointment was specially extended at the end of 1931, has now completed his term of service.

DR. R. R. MARETT, Rector of Exeter College, Oxford, has been appointed Donnellan lecturer for 1933 in Trinity College, Dublin. The lecture will probably be delivered in the second week in May. An earlier date than usual is being arranged to suit Dr. Marett's other engagements. He has announced the subject of the lecture as "Pre-theological Religion in Feeling, Thought and Action".

A COURSE of four public lectures entitled "An Introduction to Indian Archæology" will be given by Mr. F. J. Richards, honorary lecturer in Indian archæology at University College, London, beginning on Tuesday, January 24, at 5.30 P.M., and thereafter at the same time on each Tuesday until February 14. The subjects of the lectures will be: physical factors; human factors; religious complexities; arts, useful and otherwise. The lectures are open and the public will be admitted without fee or ticket.

BY arrangement with the Polytechnic, Regent Street, London, and the National Illumination Committee and the Illuminating Engineering Society, a course of ten lectures on illumination will be given at the Polytechnic on Wednesdays beginning February 8. The lectures will deal with various aspects of illumination and will be delivered by experts in the respective subjects. Further information can be obtained from the Director of Education, The Polytechnic, 309 Regent Street, W.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A wholetime abstractor and translator (at Sheffield) for the Safety in Mines Research Board—The Under-Secretary for Mines, Establishment Branch, Cromwell House, Dean Stanley Street, Millbank, London, S.W.1 (Feb. 4). A public and agricultural analyst and gas examiner for the County of Derbyshire—The Clerk to the County Council, County Offices, Derby (Feb. 4). A librarian for the Halesowen Urban District Council—The Clerk, Cornbow House, Halesowen (Feb. 10). A specialist in biochemistry and physiology in relation to food and nutrition on the medical staff of the Ministry of Health—The Director of Establishments, Ministry of Health, Whitehall, S.W. (Feb. 13). A metropolitan meat industry commissioner for the Government of New South Wales—The Minister for Public Works and Health, Department of Public Health, Sydney, Australia (March 31).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Characteristics of Highly Active Vitamin A

THE recent publications of Karrer, Morf and Schöpp[1], and of Heilbron, Heslop, Morton, Webster, Rea and Drummond[2], have pointed to the conclusion that the highest concentrations of vitamin A they were able to obtain were almost pure. We have recently been able, by the help of high-vacuum technique, to prepare a much more highly active vitamin A. The physical data relating to our preparation are recorded below.

For the final stages of purification a pumping system with a limiting pressure of 10^{-7} mm. was employed, and the vacuum was of the order of 10^{-5} mm. The conditions of distillation were such as to secure vaporisation with as small a path of traverse as possible for the molecules from the evaporation surface to the condensation surface, the mean distance being 12 mm. for an evaporation area of 30 sq. cm. Provision was made to regulate the heat input so that the end point of distillation of the various fractions might be as sharp as possible, a temperature advance equal to about 5°–7° C. being necessary to bring about the commencement of distillation of the next higher fraction after removal of the main fraction. By this means it was possible to effect separative distillation over a range of temperatures between 115° and 170° C. The fraction boiling between 136° and 137° C. gave physical constants and figures on analysis which lead to the conclusion that the substance is a purer vitamin A preparation than has hitherto been described. They are as follows :—

The antimony trichloride blue value is 78,000.

Spectroscopic figures :

(1) From the colour produced with antimony trichloride

$E \left\{ \begin{matrix} 1 \text{ per cent} \\ 1 \text{ cm.} \end{matrix} \right.$	693 mμ.	465
	617 mμ.	5,000
	580 mμ.	2,600

(2) Direct spectrophotographic measurement :

$E \left\{ \begin{matrix} 1 \text{ per cent} \\ 1 \text{ cm.} \end{matrix} \right.$	328 mμ.	1,600

The figures for the purest vitamin A previously obtained by Heilbron and his colleagues were: Antimony trichloride blue value of 65,000.

(1)	$E \left\{ \begin{matrix} 1 \text{ per cent} \\ 1 \text{ cm.} \end{matrix} \right.$	693 mμ.	450
		617 mμ.	4,650
		580 mμ.	2,550
(2)	$E \left\{ \begin{matrix} 1 \text{ per cent} \\ 1 \text{ cm.} \end{matrix} \right.$	328 mμ.	1,370

Ultimate analysis gave the following figures: $C = 83 \cdot 5$ per cent, $H = 10 \cdot 6$ per cent, which are in excellent agreement with the formula suggested by Karrer, $C_{20}H_{30}O$, requiring $C = 83 \cdot 9$ per cent, $H = 10 \cdot 5$ per cent. It has also been found that the product in alcoholic solution shows no optical rotation.

The biological test showed that 0·0006 mgm. a day administered to rats gave slightly better growth than 0·001 mgm. (or 1 unit) a day of International Standard Carotene. This dose sufficed to cure xerophthalmia.

We desire to express our thanks to Miss K. Culhane for the biological test and to Prof. Heilbron and Dr. Morton for much help with the analysis and physical determinations.

FRANCIS H. CARR.

Irradiation of Nucleic Acids and Uracil

GUHA and Chakravorty[1] recently announced the formation of vitamin B_1 by the ultra-violet irradiation of adenine sulphate. We wish to report similar experiments with nucleic acids and uracil.

Studies of the relation of the constituents of the cell nucleus to the effects of ultra-violet light on cells led us to examine the absorption changes of these materials upon irradiation with various ultra-violet wave bands[2]. In the course of these investigations, we were struck by the fact that modifications of the spectra of these materials upon irradiation—more particularly if wave-lengths shorter than 2900 A. were excluded—brought them into close resemblance to the spectra of certain B_1 concentrates[3]. The similarity of the sources of B_1 and these materials, and the observation that uracil and adenine acquire the ability upon irradiation of reducing arsenophosphotungstate solutions[3]—a colour test held by some to be a property of vitamin B_1—suggested that B_1 might be a modified purine or pyrimidine of the type produced by the irradiation of such materials.

In most of the experiments by which we undertook to test this hypothesis, thymus and yeast nucleic acids were used, since, as each contains four nitrogen bases, any activation of either or all of these to any or several of the components of the vitamin B complex might, we thought, be so secured. The injection of irradiated nucleic acids into polyneuritic rats appeared in some instances to indicate moderate vitamin B_1 activity. Indeed, one apparent cure resulted from the administration of irradiated uracil. But careful examination of the results with large numbers of animals made it appear that the positive effects should be attributed to variability of the rats, and it was necessary to conclude that ultra-violet irradiation was probably ineffective in producing vitamin B_1 from these substances. Our irradiated materials were also tested for vitamin B_2 potency, with negative results. A paper by one of us describing these experiments is now in press[4].

The negative results are borne out by the fact that our more recent spectrographic work[5,6] indicates vitamin B_1 to be characterised by a maximum at 2600 A., whereas the absorption changes believed at first to be associated with the production of vitamin B_1 were mainly in the shorter wave region[2]. Our studies of the absorption spectrum of irradiated adenine sulphate[2] show it to be less, rather than more, similar to what we now believe to be the characteristic spectrum of vitamin B_1[5,6].

The reported finding of sulphur in the most potent vitamin B_1 concentrates[7], is another factor which now makes it seem unlikely that any sulphur-free base could yield vitamin B_1 upon irradiation. That irradiation could introduce sulphur as an integral part of the molecule from the sulphuric acid bound by the base appears a very remote possibility.

Aside from these arguments, it is possible that if adenine is the only precursor of vitamin B_1 in the nucleic acids, one might fail to find activity upon irradiating nucleic acids, but succeed in finding it upon irradiating adenine sulphate, either because of the higher concentration of the material capable of activation in adenine sulphate solutions, or because the chemical binding of adenine to other constituents might prevent its activation when a part of the nucleic acid molecule.

Meaning of Neoteny and Pædogenesis

FOR a scientific term to be of value it is absolutely necessary that in all circumstances it should be used with strict regard for its definition; otherwise only confusion of thought and faulty argument can result. This should be obvious, but unfortunately some terms readily lend themselves to misuse. 'Pædogenesis' and 'neoteny' are terms the definitions of which have been treated with very scant respect. Because of the confusion that has resulted it seems desirable that attention should be directed both to the origins of these words and to their real significance.

The term 'pædogenesis' was first proposed in 1866 by K. E. von Baer[1] who was writing of the phenomena which had recently been observed in *Miastor*, and it is quite clear that he regarded pædogenesis as a form of parthenogenesis. The fact that von Baer regarded parthenogenesis as a form of asexual reproduction does not affect the definition.

O. Hamann[2] (1891), when he described an Acanthocephalan which became sexually mature in the larval stage, was one of the first to misuse the term 'pædogenesis'. This was noticed by Chun,[3] who when defining 'dissogony' protested against Hamann's use of 'pædogenesis'. It may be noted here that Hamann was the first to propose the idea of evolution taking place on a large scale by means of 'pædogenesis', an idea which in a modified form finds favour with some modern authors, notably Prof. W. Garstang[4] and Mr. G. R. de Beer.[5]

Kollmann[6] was the first to use the term 'neoteny', and he used it to describe the phenomena which had been observed in the Amphibia. He distinguished between 'partial neoteny', which is said to occur when metamorphosis is delayed beyond the normal period, for example, the wintering of certain tadpoles; and 'total neoteny', which is found in the case of the Axolotl, where the animal retains its gills but becomes sexually mature.

'Neoteny' and 'pædogenesis' therefore indicate two distinct phenomena. In 'pædogenesis' a form of parthenogenesis is found, but in 'neoteny' we see a case of normal sexual reproduction. The distinction between the terms is clear cut and is of biological importance.

In re-defining the terms under discussion, Mr. de Beer has disregarded their origins and the definitions of their authors. So he uses 'neoteny' as a wide term which implies an alteration in the rate of development of the germen as compared with that of the somatic tissues: an idea which cannot be brought into line with Kollmann's views. This alteration may be brought about in a number of ways; if by the speeding up of the rate of ripening of the germen, that of the somatic tissues remaining constant, 'pædogenesis' will result, and Mr. de Beer considers that the most perfect cases of this are those of *Miastor* and *Polystomum integerrimum*; if the acceleration has not proceeded so far a case like that of the Axolotl will result. On this view all these cases are different aspects of the same phenomenon.

It is very doubtful whether the matter should be considered in this way; it would appear to be giving the status of a fundamental biological concept to the observed fact that in a few isolated cases in the animal kingdom the normal relation between the rates of ripening of the germen and of the somatic tissues, as judged by observations on the majority of closely related species, has become modified.

That such a state of affairs has been brought about by changes in the external environment is undoubted, and in the case of the Ctenophores described by Chun[7] this is abundantly clear. It is impossible therefore to consider the sporadic occurrence of the early ripening of the germen as more than a fortuitous happening; and it would appear to be of more value to use the words 'pædogenesis' and 'neoteny' to distinguish forms of parthenogenesis and normal sexual reproduction respectively than to combine under them isolated examples having no biological relationship and drawn at random from all over the animal kingdom.

We are thus brought to the conclusion that the cases of the Axolotl, the Ctenophores and the Acanthocephala are cases of 'neoteny', whilst 'pædogenesis' occurs only in the insects; the case of *Polystomum integerrimum*, in which the fusion of gametes is said to occur, must be regarded as 'neoteny' in an hermaphrodite animal.

To those who incline towards the view that evolution on a large scale has taken place by the process of the shortening of the ontogeny, it may be pointed out that in discussions on this subject the older definitions of 'pædogenesis' and 'neoteny' are of great importance, for it is obvious that if the ontogeny were to be shortened in a truly pædogenetic form sexual reproduction would be lost to that species.

In conclusion it must be noted that 'dissogony' must be regarded as a form of 'neoteny', Chun himself having compared the phenomenon which he had observed with the case of the Axolotl, and contrasted it with the phenomena seen in *Miastor*.

Oxidase of the Crystalline Style

MY observation of the occurrence of an oxidase system in the crystalline style of *Saxidomus giganteus, Paphia staminea* and *Mya arenaria*[1] has been confirmed by Yonge in that of *Ostrea edulis*, but in this case the reaction of the style extract to guiacum was found to be extremely feeble[2].

Recently I have had the opportunity of testing the crystalline styles of three species of oyster (*O. virginica, O. lurida* and *O. gigas*) for oxidase and have found the reaction to guiacum quite marked. There is considerable variation in each case in the activity of extracts made under identical conditions from different batches of crystalline styles, depending, apparently, on the condition of the styles, which is affected very quickly by small changes in environment, but each species has yielded extracts equalling, or exceeding, in oxidase activity those from *Saxidomus giganteus* made in precisely the same way and tested with guiacum.

In addition to those species already mentioned, *Schizotheurus Nuttalli, Cardium corbis* and *Bankia (Xylotrya) setacea* have now been found to contain the oxidase system in their crystalline styles. It is probably of general occurrence in the lamellibranchs.

Nutritional Condition of Sheep and Susceptibility to Stomach Worm

THE important influence of the nutritional condition of the host in resisting worm infestation has been demonstrated by Zimmermann *et alia*[1], Ackert *et alia*[2,3,4] in chickens, Foster and Cort[5,6,7] and Nagoya[8] in dogs, Kobashi[9] and Chandler[10] in rats. The problem is one of supreme importance in sheep, the parasitic infestation of which frequently constitutes a limiting factor in the carrying capacity of pastures. The number of sheep on a farm may be limited by the potential infectivity of the pasture, rather than by the amount of grazing it provides. Since the information derived from the experiments of these workers would appear to have a very important bearing on the control of parasitic gastritis in sheep, an experiment was commenced in the spring of 1932 to determine the degree to which differences in clinical condition produced by nutritional means might affect the degree of parasitic infestation of sheep exposed to an equal chance of infection.

Forty lambs were taken from their dams soon after birth and fed in concrete pens (sawdust used as bedding) on cow's milk, meals and grass cut from pastures which had never been grazed with sheep or cattle. At the age of three months the lambs were divided into two groups of sixteen (eight having died), the two groups being comparable in weight and appearance. One group was given 7–8 lb. of green tares and oats per head daily. The other group received, in addition to the tares and oats, three pints of separated milk and one pound of mixed meals daily. Fæcal examination on three separate occasions showed that no helminth eggs were being passed.

When four months old the lambs were grazed on worm infested pasture. At this period the average weight of the poorly-fed group was 60 lb. and of the well-fed 84 lb. The well-fed group continued to receive 1 lb. a head of meals, but the separated milk was discontinued.

After six weeks grazing the lambs were slaughtered, their fourth stomachs removed intact and the worms counted. The average number of worms in the poorly-fed group was 103, in the well-fed 31. There was a surprising individual variation within each group, the numbers in the poorly-fed group ranging from 0 to 222 and in the well-fed group from 2 to 76. Statistical analysis of the results, kindly undertaken for us by Dr. Tocher, showed that the difference between the two groups was significant and that the chances against the group difference being fortuitous were 1,400 to 1.

It may therefore be deduced that under natural conditions of infection, the nutritional state of the sheep plays a significant part in determining the degree of its susceptibility to stomach worm infestation.

Local Lists of Animals

MAY I make a mild protest against the rather derogatory remarks about local lists of animals in the notice of Bolam's "Birds of Northumberland" in NATURE of December 3 (p. 841)? Natural history studies have made great progress in recent years by the methods practised by Mr. Nicholson, Mr. Elton and others, which find expression in the excellent new *Journal of Animal Ecology*. But because the new is very good, it does not follow that the old is bad : the two are surely complementary.

Local lists are the basis of our knowledge of geographical distribution and there is still plenty to be done at that. The facts for the various groups of animals in Britain are certainly not yet fully known ; even when the data must be adequate (for example, Lepidoptera, Coleoptera) they have not been put together as they have for plants and Mollusca and so made generally available. I much hope that before long the Entomological Society and similar bodies will see that this is done ; it will make the interest of internal distribution much more obvious.

The time, too, is just coming when local lists are beginning to have some historical interest ; some things have remained as they were, some have changed, and changes are, I believe, of more than usual interest among the very birds with which the note in NATURE deals.

These considerations concern the benefit of naturalists in general. Local lists are also of great help to the individual who likes going about the country trying to understand what he sees, because they give him some definite object in pursuit of which he picks up all sorts of good knowledge.

It is, I suppose, just a natural human passion to like to have something definite to do, just as it is to find out something which no one else knows. To observe the beetles of the parish of Edvin Loach in a diffuse and general way probably leads nowhere except to an interest in something else; to set out to make a list of them is a defined purpose which will have the stimulus and joy of approximate achievement and be punctuated by exciting discoveries—new to the parish, new to the county, possibly new to Britain. Incidentally, it will lead to the accumulation of a great deal of knowledge of how the local beetles live and breed, and possibly to the differentiation of fresh forms; the list will, of course, be all the better if some of this is incorporated.

Local lists are, in short, one of the classical techniques of natural history in Great Britain; they have been the framework in which much of the best work has been set, and there is, I think, every reason to expect that the method will be equally fruitful in the future. The average naturalist has not generally got very much spare time and he cannot be a trained scientific biologist, but he can and does serve the same ideal to very good effect.

Dec. 10. A. E. BOYCOTT.

Inheritance of Acquired Characters

IN NATURE of October 1, p. 508, is published an interesting communication from A. F. Dufton to the effect that the fathers of eminent persons tend to be older at the time of birth of the eminent (or shall we say pre-eminent?) child than is typical of fathers of children who do not attain eminence. Mr. Dufton's communication is a confirmation on a more extensive scale of a relationship reported by Francis Galton[1], A. H. Yoder[2], and Havilock Ellis[3], in their more limited studies. It is in keeping with the discovery by Minnie L. Steckel[4] of a positive correlation between age of parent and intelligence of child among the school population of Sioux City, Iowa.

In NATURE of October 15, Dr. R. A. Fisher comments upon Mr. Dufton's letter, one of his suggestions being that "A more satisfactory comparison would be between the ages of paternity for eminent persons, and those of their less eminent brothers and sisters". This comparison has been made upon small series by Yoder and by Ellis with conflicting results. Yoder[2] found the distribution of great men in the older as compared with the younger half of the sibship to be 24 to 13. Ellis[3] found a slightly greater frequency of genius in the position of first-born than of genius in the position of last-born (97–67).

There is available, however, more direct evidence of a positive relationship between parent age and intelligence (or between birth order and intelligence, since parent age and birth order are at present inextricably interwoven). In a study[5] of children examined at the Illinois Institute for Juvenile Research there was found to be a definite tendency for later-born children to exceed their earlier born siblings in intelligence quotient. This finding was confirmed by Dr. Steckel[6] in a study of nearly 7,000 children in the school system of Sioux City, Iowa. In both of these studies, comparisons were made only between siblings and in this way any possible distortions resulting from a correlation of intelligence with age of marriage or family size were eliminated. That these findings were not due to an inadequate standardisation of the tests is indicated by the fact that these relationships were still present when test results were re-standardised upon the child populations from which this sibling material was drawn.

While it is entirely possible to explain this relationship by assuming the inheritance of acquired characters, it is, as Dr. Fisher points out, by no means necessary to make this assumption. Parents are apt to be more experienced in child training and in better economic condition when their later children arrive and it is difficult to judge the possible advantage which an older sibling may give to a younger child's intellectual development. If an explanation is to be sought upon the biological level, I personally should be more inclined to seek it in the physiological effects of the prolonged labour and difficult deliveries with their attendant risk of brain damage which are more common with the earlier born children, than in the inheritance of acquired characters.

The question of order of birth in relation to the development of the child has also been discussed at some length by H. E. Jones[7].

A Method of Extending the Frequency Range of the Cathode Ray Tube

THE cathode ray tube could be employed on several present-day problems if records could be obtained at somewhat higher frequencies than those obtainable at present. The use of brighter tubes, lenses of wider aperture, faster films and higher film speeds should achieve the required improvement. With regard to lenses, where a cinema lens is used the following arrangement should be found useful:—A long focus collimating lens receives the light from the cathode ray tube and renders the rays parallel. A short focus cinema lens of large aperture receives these parallel rays and focuses them on to the photographic emulsion. The reason for using two lenses in preference to a single lens is that these lenses are usually designed to receive parallel rays, and therefore if they receive rays which are not parallel the definition suffers unless the aperture is reduced. It will be noticed that the collimator is a long focus lens compared with the convergent lens. In consequence a reduced image of the end of the cathode ray tube is formed in the plane of the photographic plate or film.

The advantage of this arrangement is that since the image is smaller than the object, the spot of illumination on the plate is correspondingly smaller than that on the end of the cathode ray tube. Consequently, if the plate is moving at a constant rate at right angles to the deflection of the cathode ray, the precision of observation in the direction of travel will be increased in the same proportion as the size of the spot is diminished. Now the brightness of the spot is also correspondingly increased so that the exposure of any given part of the plate is correspondingly increased. Three alternatives present themselves: (1) to use the usual speed of plate and increase the deflection, in which case the precision of measuring the deflection will be increased in proportion; (2) to increase the speed of the plate, in which case the precision of measuring in the direction of travel is still further increased; (3) to decrease the speed of the plate, in which case it is the precision of measuring the deflection which is increased. These alternatives are summarised for a case in which there was a ten-fold reduction in the size of the image in the following table:

Alternative schemes.	Speed of plate.	Accuracy of measuring deflection.	Accuracy of measuring in direction of motion of plate.
(1)	1	×10	×10
(2)	×10	1	×100
(3)	÷10	×100	1

From a consideration of other cases it is found that the product of the improvements shown in the last two columns is approximately equal to the square of the linear reduction in the size of the image. All the above figures have been calculated on the assumption that the aperture of the lens system at the tube is a constant one. The data given above show that accuracy is improved the more the image is reduced in size by the lens system. A limit to the improvement is set by the grain of the photographic emulsion, by the difficulty of designing lenses of large aperture and adequate definition, and also by inaccuracies present in the optical instrument used for making measurements of the photographic records which are obtained.

With regard to suitable lenses there appears to be a definite need for a special lens for cathode ray work. A lens having a numerical aperture of 0·8 or 0·7, a focal length of 25–50 mm. and adequate definition on the film over an area of 3–5 mm. would be useful, on the lines of a well-corrected microscope substage condenser. The end of the modern cathode ray tube which presents to the lens a convex surface makes the obtaining of good definition difficult. It would be better from the optical point of view for the surface presented to the lens to be concave. This might be done by coating a suitably curved glass surface with the fluorescent material and by placing this inside the bulb of the cathode ray tube.

With regard to the camera, since film speeds between 10 and 100 metres per second will be required, the use of the ordinary spools and gate would present difficulties. A suitable alternative would be a motor-driven drum with the film wound round its circumference. Exposures on film ½–1 m. long could be obtained in this way. A method of exposing such a rapidly rotating film during one revolution only is to drive a worm wheel from the shaft of the film drum, this worm wheel carrying contacts which short circuit the charge on one of the deflector plates of the cathode ray tube. Prior to and subsequent to the short circuit the cathode ray is deflected behind a screen, so that the illuminated spot does not enter the lens. During the temporary short circuit the spot oscillates about its central position and its movements are photographed. With a worm wheel of 20 cm. in circumference driven at one hundredth the speed of the drum the short circuit contacts should be 2 mm. long.

Longer exposures than those given by a single drum rotation could be obtained by winding the film in a spiral round the drum and causing the lens system to move sideways during exposure, so that the image corresponds approximately to the centre of the film during exposure.

Capacitance Hygroscopy and some of its Applications

BEING myself concerned with the properties of both soil and cotton, I read with particular attention the article on this subject by Dr. Lawrence Balls in NATURE of December 17. I have found it difficult to decide exactly how Dr. Balls considers the moisture content of the soil or cotton bale under test affects his condenser reading. From his opening paragraph one might conclude that he believes the dielectric property of water to be the dominant factor. Later, however, he remarks that "variations of resistance in the unknown capacity can also alter the 'capacitance' readings". An instrument which responds to changes in electrical resistance is influenced by the salt as much as by the moisture content. One responding to the high dielectric constant of water contained in a material would, on the other hand, be most valuable. There are some who might easily be misled into thinking that a dielectric constant is involved merely because condensers are used in the measurement. In view of the statement I have quoted, it appears that Dr. Balls is aware that his apparatus measures the equivalent parallel capacity of the system tested.

Suppose a condenser of capacity C and resistance R were connected in series, and tested, the 'capacitance' would be $C/(1 + R^2\omega^2C^2)$. If, for example, $C = 100\mu\mu F$, and $R = 1,000$ ohms, at a frequency of 2,000 kc., $R^2\omega^2C^2 = 1\cdot66$, and the 'capacitance' measured would be $37\cdot6\mu\mu F$. If R rose to 2,000 ohms without any change in C, the value would be only $13\cdot1\mu\mu F$. The systems investigated by Dr. Balls are, of course, more complex than this; but there is nothing in his article to show that the 'capacitance' changes which he observes are not mainly due to resistance effects.

The matter can easily be settled by finding how sensitive the 'capacitance' readings are to frequency. If, in the simple case taken above, R were so high as 10,000 ohms, $R^2\omega^2C^2$ would be large in comparison with 1, and the 'capacitance' measured would be substantially $1/R^2\omega^2C$. The value obtained would therefore change inversely as the square of the frequency, and would *fall* with *increase* of C.

In more complicated systems the issue is less clear-cut; but in cases where the measured 'capacitance' varies inversely with the frequency raised to a power between 1 and 2, it is not justifiable, when deducing the properties of the material between the electrodes, to assume it to be a non-conducting dielectric. The frequency test is easily applied, and until the results of it are forthcoming, we are not in a position to place a precise interpretation on Dr. Balls' results.

There is one further point that deserves comment. In connexion with his results with soil, Dr. Balls remarks: "Some very complex curves for changes in soil-capacity with change of moisture have recently been published, determined by a compensated bridge method. They contrast very sharply with such simple curves as Fig. 2, which seem to me to be more inherently probable." These "complex curves" were obtained by Mr. G. H. Cashen of this Station, and the reason advanced for setting them aside does not seem to me at all convincing. I am inclined to regard simplicity as a craving of the human mind rather than a reality of Nature. In any event, Dr. Balls could probably learn a lot about what takes place at the surface of the iron hoops of his cotton bales by employing a method of as critical a nature as that used by Mr. Cashen; 'surface' or 'electrode' capacity must certainly enter in here.

Heights of Nuclear Potential Barriers

As a result of experimental work in the past few years on the artificial disintegration of light nuclei and the nuclear scattering of α-particles, we now have a means of estimating the heights of the potential walls surrounding these nuclei. I have collected the evidence from a variety of sources which can be summarised as below.

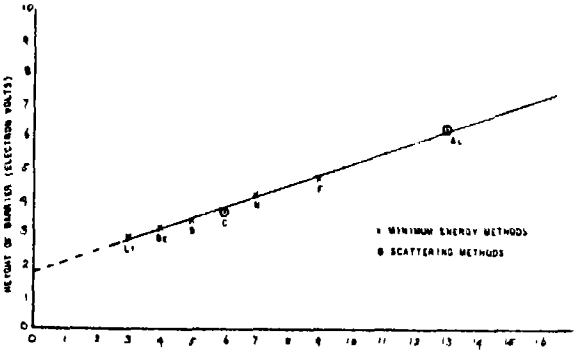

Fig. 1.

(*a*) *Minimum energy methods:* Here the value of the range of the α-particle of least velocity which will enter the nucleus and cause the emission of either a proton or a quantum of radiation is found. The energy of this particle will correspond to the height of the nuclear barrier.

(*b*) *Scattering experiments:* The anomalous scattering of α-particles which make close approach to the nucleus gives a measure of the probability of their entry within. The radius of the nucleus for which this scattering is appreciable can be estimated and from this we can deduce the smallest potential for which an observable penetration takes place: this will correspond to the height found by the minimum energy methods.

The heights so found (given in terms of the potential of an α-particle of charge 2) are plotted against atomic number, giving a straight line (Fig. 1).

This therefore suggests the simple rule that *the heights of the nuclear barriers of the light elements are proportional to the atomic number.*

If this relation is true outside the limits of the elements for which evidence exists, then we must conclude that the protons produced from phosphorus by α-particles from polonium (energy $5 \cdot 2 \times 10^6$ electron volts) and potassium with radium C (energy $7 \cdot 6 \times 10^6$ electron volts) are due to resonance with a virtual α-particle level, since the α-particle will have insufficient energy to surmount the barrier.

The full details of the calculations will be published shortly.

Corrections to the Times of the *P* Wave in Earthquakes

A REDISCUSSION of about eighty earthquakes from the International Seismological Summary is in progress. Revised epicentres and apparent times of starting have been found, the revised tables of *P* recently published by one of us being used. The *S* tables were not used because it was known that the identification of *S* is less trustworthy than that of *P*. The new residuals of *P* show that the correction needed at distances near 30° is somewhat larger than was found before. In East European and North American earthquakes the tables seem accurate to 15°, but need a correction rising to + 1s. at 19°. Then there is a sharp bend in the curve, the corrections needed reaching − 5s. about 30°. They remain negative to 58°, and then are positive to 70°, the greatest correction being + 2s. At greater distances the corrections needed are small.

Japanese earthquakes show a similar behaviour up to 50°, but beyond that distance they are not suited for determining corrections, since an error in the tables has the same effect on the residuals at the European stations as a displacement of the epicentre to the north-west, which cannot be checked on account of the distribution of the near stations. Oceanic earthquakes seem to show no need of corrections near 30°, but the small number and uncertainty of the observations make the probable error of the times large.

Byerly noticed the bend near 20° in the observations of the Montana earthquake, but it remained to be seen how general it was. Miss I. Lehmann has also, we understand from a letter, detected it in an Azores earthquake. Our data would agree with the existence of a discontinuous increase of velocity with depth, but Miss Lehmann's study of original seismograms seems to favour a continuous though rapid transition.

Viscosity Measurements of Liquids by the Oscillating Disc Method

WITH reference to the advantage of this method described by A. van Itterbeck[1], it may be said[2] that another advantage it has over the capillary stream method lies in the insensitivity of the disc experiments to the presence of dust particles as compared with the sensitivity of the capillary method.

While, however, the disc method has its advantages in experiment, those who have used this method would probably agree that the accurate calculation of the absolute or relative viscosity of a liquid from the logarithmic decrement is not so satisfactory as the calculation from the capillary method.

Research Items

Symbolism of the Maze. In *Antiquity* for December Mr. W. F. J. Knight offers the suggestion that the design of the pattern stone of Bryn Celli Ddu is an inaccurately rendered maze formation. He points out that this motive, or the cognate motive of the spiral, occurs on one of the upright stones, and is also the actual structural design of the monument itself. It is assumed that the best kind of explanation of this triple occurrence is some form of magic—a maze embodying the ideas of defence and exclusion and of penetration of the defence. Maze ritual can be identified in the history of the maze form. The Troia, or 'Trojan game', appears to have been a ritual ride of armed horsemen practised in early Italy. Mazes are generally called 'Troys' in northern Europe. Virgil compares the movements of the Trojan game to the intricacies of the labyrinth at Knossos. A maze ritual was connected with the Eleusinian mysteries, the underlying idea being the initiation that leads to perfection, or the penance that leads to Paradise. The maze is also a symbol of secrecy, as in the story of Fair Rosamund. The sacred dance of the Salii at Rome, a protective processional, has been called a 'Troia on foot'. Both Saliian dance and Troia emphasise the distinction between within and without. Thus a maze becomes a protective wall of great magical strength with an entrance difficult for the unauthorised. It would appear that the name Troia is not a literary association, but is connected with a Latin verb denoting some kind of active movement. Troy, therefore, may have taken its name from the game and not vice versa. The connexion between the sites and beliefs of classical antiquity and bronze age Britain is probably to be sought in the rites of the British tumulus folk around their tumuli.

Yuman Music. Miss Densmore's studies of the music of the American Indians have covered Indians of woodlands, plains, high plateau and desert cultures. The songs she has collected among the Yuman and Yaqui of the River Colorado and north-west Mexico (Bull. 110, Bur. American Ethnol.), by contrast, belong to a river culture, based upon a rude, but efficient, agriculture, without irrigation and supplemented by hunting, and a life in settled villages. Among the Yuman the characteristic musical form consists of cycles of songs which are interpreted in legends. Some of the legends can be related in about nine hours, while others are longer. The story is told in the common language, but that of the songs is old and cannot be understood by anyone, the songs being learnt with the music by rote. The songs are episodic to the narrative. There is dancing in a few, but not all, of the cycles. In the deer dance and the corn dance only of those described do the dancers encircle the musicians. The characteristic form of the songs is periodic with one, two, or occasionally three, long periods and one short period containing the most pleasing part of the melody. There are rules for the repetition of the periods, but they are not strictly observed, especially by a good singer. Often they are sung for a larger number of times than is prescribed by the rule. The accompaniment shows great variety in rhythm. The songs are accompanied by rattle and by basket drum and also by nasal grunting and the pounding of feet. The grunting was used especially in hunting songs. There were two varieties of flute, and although there were no love songs, they were used by players standing in a group to attract the attention of the girls.

Measurement of Visual Acuity. In a report to the Medical Research Council (Special Rep. Ser., No. 173. London: H.M. Stationery Office. 1*s*. 6*d*. net) R. J. Lythgoe and Dorothy E. Corkill deal with the relation between visual acuity and illumination. Visual acuity, which in the wide sense includes the ability of the visual apparatus to appreciate contour differences, discrimination of two points, and legibility, is dependent upon physical, physiological and psychological factors. It is still widely held that visual acuity is at a maximum at an illumination of 3–4 foot-candles, and artificial illuminants giving more than 10 foot-candles are sometimes condemned. Values of more than a hundred times this figure are, however, frequently met with, and there is no doubt that acuity is considerably better under these high illuminations, though the rate of improvement is a constantly diminishing one with illuminations higher than 100 foot candles. High values of visual acuity are obtained only when the illumination falls on the periphery of the retina. The effect of glare was investigated; when the surrounds are dark, glare may increase visual acuity, but in an adequately illuminated room causes a fall. Another important aspect of the subject is dark adaptation; thus, the performance of a ship's outlook is defective if insufficient time elapses for dark adaptation or when there are bright lights in the field of vision. For accurate testing of visual acuity it is important to employ illuminations of more than 25 foot-candles, in a moderately light room. It is found that in commercial test-types the errors in the letter commonly exceed 10 per cent.

Forecasting the Herring Fishery off East Anglia. The readings of the annual rings upon the scales of herring and their correlation with the size of the fishes have given a clue to the sorting out of herring shoals in year groups. This in turn reveals the years which are prolific in young fish, and enables the fate of any year-group to be traced through succeeding years. Always provided that the sampling of the shoals provides a fair picture of the proportions of the year-groups and that the scientific analysis is accurate, these methods allow of an approximate forecast of the potentiality of the fishery for several years ahead. Dr. W. C. Hodgson summarises the results of his analysis of East Anglian herring shoals from 1923 until 1931, and shows how the data for 1923–30 were used to make a forecast of the 1931 season, the estimated result showing a close agreement with the actual catch (*J. Animal Ecology*, vol. 1, p. 108, 1932). Forecasting the herring stocks in the southern North Sea began in 1929, and, considering that the method is still in the experimental stage, have been reasonably accurate. But although the forecast can foretell the relative proportions of different year-groups, it cannot be taken as an accurate indication of the total amount of the catch, since this depends also upon extraneous factors, such as the suitability of the weather for fishing operations or the intensity with which the fishing is prosecuted, which in turn depends upon the potential demand for the catch.

Schistosomiasis in the Philippines. The occurrence of schistosomiasis japonica or katayama disease was recorded for the first time in the Philippines in 1906. The organism concerned is the Oriental blood fluke *Schistosoma japonicum*, but knowledge concerning its molluscan intermediate host in those islands has been greatly needed. In a recent paper (*Phil. J. Sci.*, 49, No. 2, 295–304; 1932) Mr. Marcos A. Tubangui discusses this subject and announces his discovery that the snail *Blanfordia quadrasi* has been found by him to be infected with cercariæ similar in every respect to those of *S. japonicum*. The snail occurs in moist places on the banks of small bodies of freshwater, and samples of the mollusc, collected near houses occupied by persons suffering from the disease mentioned, were found to be naturally infected. When the cercariæ were successfully introduced into mice and other laboratory animals the adult flukes, into which they developed, were similar to those of *Schistosoma japonicum*. The snail was further proved to be the missing intermediate host of the blood fluke by successfully infecting it with the miracidia stage of the parasite.

Root Nodules and Nitrogen Fixation. As No. 5 in the University of Wisconsin Studies in Science has appeared a sumptuous volume upon the "Root Nodule Bacteria and Leguminous Plants", by E. B. Fred, I. L. Baldwin and Elizabeth McCoy. This monograph reviews critically and adequately the enormous literature dealing with this subject and contains also a very judicial summary of the attempts made upon a commercial scale to supply the causal organism of the nodules to farmers. It is interesting to read the conclusion that nitrogen fixation in pure cultures of the nodule organism outside the plant remains still unsatisfactorily established, though the gain in nitrogen from the air by the activity of the living contents of the nodule is beyond doubt. The authors point out that different types of nodule, with different distribution on the root system, may have very different values. They conclude that the best results are obtained when the nodules are relatively few in number and large in size and borne on the tap root and the main laterals. A commonly accepted theory that comes out badly from this critical study is the view that the nodule is to be regarded as an abortive branch root. At the same time, the authors give little indication of the manner in which the vascular tissue develops within the nodule. They review briefly work upon root nodules on plants outside the Leguminoseæ and also upon the few cases where bacteria are reported as regularly associated as symbionts with leaves. In this review the root nodules of *Casuarina* receive very brief notice but Aldrich-Blake now publishes a note (Oxford Forestry Memoirs, No. 14, 1932) which would add *Casuarina equisetifolia* to the list of plants in which growth is materially improved when nodules are produced on the roots as the result of infection by a mixture of crushed nodules and soil.

Landslide at Toge, Japan. Two papers, by Prof. N. Nasu and Prof. N. Miyabe, have recently been published on this landslide (*Earthq. Res. Inst. Bull.*, 10, 674–693, 694–700; 1932). At the end of November 1931, it was found that at the village of Toge (about 12 miles south-east of Osaka), a land-block covering about eighty-one acres was slowly sliding downwards in a southerly direction. The block is bounded on all sides but the south-east by a zone of cracks, one on the west margin being a trench 550 yd. long and 88 yd. wide. The slope of the sliding area is about 15°. The landslide is of interest, not so much for its size, though it is one of the largest known in Japan, as for the various modes in which its displacement is being measured. Prof. Matsuyama carried out triangulations and precise levellings over the whole area. At the beginning of last February, Prof. Nasu installed recording instruments at points on the northern margin nearly 200 yd. apart. The motion of the mass was found to be very rapid. On February 20, the western station descended 6 in. and the eastern 13 in. The records, though on the whole nearly straight lines, show minute fluctuations, that Prof. Nasu measured with a recorder magnifying 2,000 times. On February 18 and 28, observations were also made with dial gauges at eleven stations on the northern boundary, showing maximum displacements of 0·39 in. on the first day and 0·28 in. on the second. The tilting of the mass was measured by a pair of horizontal component seismographs erected in Toge and, on February 18, was found to be 6′ to the south and nearly 4′ to the east. At the time of writing (June 20), the landslide was still going on.

Size of Fog Droplets. A paper entitled "On the Size of Fog Droplets" (*Sci. Papers Inst. Phys. Chem. Res.*, Tokyo, No. 391) by M. Kinoshita and K. Uchiyama, contains some information of meteorological interest relating to the size of the water droplets in artificially produced fog. Frequency curves are given for the distribution of different diameters of droplet in fogs produced in three different ways, namely, (1) by condensing low-pressure steam in a metal tube 15 cm. in diameter and 200 cm. in length surrounded by a water jacket for cooling, (2) by mixing air at a temperature of about $-50°$ C. with saturated air at room temperature, and (3) by using air of 70 per cent relative humidity instead of saturated air under the conditions of (2). It was found that type (1) gave a very scattered distribution, with many droplets between 2μ and 9μ in diameter. The other two types gave a pronounced peak of maximum frequency, at a little more than 3μ in type (2) and slightly more than 2μ in type (3). The authors point out that in experiments on the transmission of radiation through fog, experimenters would do well to study the best method of getting uniformity of size in the droplets. Their own experiments were made as a preliminary to the study of the transmission of infra-red rays through fog.

Internal Conversion of γ-rays. Two theoretical calculations of the probability of a γ-ray being photoelectrically absorbed in one of the electronic shells of the parent atom, have been published (*Proc. Roy. Soc.*, Dec.). In the first of these, by Hulme, the radiation field of the nucleus is taken as that of an oscillating dipole. The calculation differs from that of previous authors in that the accurate relativistic wave equation has been used for the planetary electron. The values obtained for some of the K-conversions of radium C agree well with the observations of Ellis and Aston. The paper by H. M. Taylor and Mott repeats Hulme's calculation for quadripole radiation from the nucleus. It is found that many of the conversions for radium B and radium C fall either on the 'dipole' or the 'quadripole' curves. This may be important for the theory of nuclear transitions, for it is shown that the dipole radiation corresponds to nuclear transitions in which the nuclear angular momentum changes by one quantum, while the radiation is in general of quadripole type for transitions in which $\Delta j = 0$ or ± 2. The paper shows that it is impossible to draw a distinction between the absorption of a γ-ray quantum and a direct interaction between the nucleus and the planetary electron. For certain nuclear transitions, it is probable that radiation is forbidden and the interaction takes place entirely within the nucleus. This may explain the 'anomalous' complete conversion of the radium C γ-ray at $1{\cdot}426 \times 10^6$ volts.

Crystal Structure of the Normal Paraffins. Dr. A. Müller has reported an investigation of the changes which take place in the crystal structure of the normal paraffins when the temperature is gradually changed (*Proc. Roy. Soc.*, Dec.). The specimens were contained in a thermostat maintaining any required temperature to one-tenth of a degree and they were examined by the reflection of copper radiation from a rotating anode tube, which allowed a reduction of the exposure time to about five minutes. Most of these substances crystallise at normal temperature with a long prismatic unit cell, but cells of lower symmetry are known for many of the hydrocarbons. When the substances are heated, the *a* and *b* axes expand much more than the chain axis of the cell. The relative lengths of these axes alter gradually in the case of the C_{21} and C_{23} hydrocarbons until the cell appears to become hexagonal. The members from C_{24} to C_{40} show a sudden transition to a new structure which tends to become hexagonal as the temperature is further raised. A rough picture of the molecular changes is given on the assumption that the molecule behaves as a rigid chain. The gradual transition observed in C_{21} and C_{23} is explained by the increase in rotational energy about the chain axis as the temperature is raised, with consequent approximation to higher symmetry. The sudden transition is pictured as a sudden rotation of the zig-zag molecules about their long axes on account of the equilibrium between the directive forces due to the long-chain part of the molecules and those due to the end groups.

Sodium Sulphite in Photographic Developing Solutions. Sodium sulphite is commonly considered to be merely a preservative for photographic developing solutions, preventing the oxidation of the developing agent by the air and also preventing yellow or brown stains on the negatives. It is now reported by Messrs. G. Gopala Rao and Madhusudanan Pandalai of the Andhra University (University College of Science and Technology, Waltair) in a communication addressed to the Editor, that the sulphite has also another function; it is said to regenerate the oxidised developing agent enabling the latter to reduce more than its equivalent amount of silver halide. It is also claimed that a mixture of quinone and sodium sulphite is capable of developing photographic plates.

Astronomical Topics

An Early Observation of the New Moon. The *Cape Times* of December 2 reports that the new moon of November 28 was seen with the naked eye in South Africa by Mr. A. W. Long and Capt. D. Cameron Swan 35 minutes after sunset, when its age was 17^h31^m. This is almost a record for South Africa; it was just beaten one Metonic cycle earlier on November 28, 1913; the age of the moon was then 16^h39^m. Observations of this kind have chronological importance, as many ancient nations began their months with the first observation of the lunar crescent, and it is important to determine the shortest interval after new moon that they would be likely to see it. The position of the moon's node is of importance in this connexion, and it will be noted that the Metonic cycle nearly reproduces this position, since the node completes its circuit of the ecliptic in 18 years 7 months.

Meteor Craters. Since the acceptance of the meteoric origin of 'Meteor Crater' in Arizona, many similar, but smaller, formations have been pointed out in different countries. Science Service for December 22 describes a paper by Prof. F. A. Melton and W. Schriever in which they ascribe a meteoric origin to a number of large holes in the Carolina States. They are elliptical in shape with their axes parallel; it is inferred that the masses producing them arrived from the north-west. Aeroplane photographs were used in tracing the outlines. The date of the impact is inferred to lie between the Pliocene and Pleistocene epochs, but cannot be fixed more closely.

Tables for Galactic Co-ordinates. Galactic co-ordinates are now of such frequent use in stellar problems that tables for conversion into them are welcome to astronomers. Prof. P. Emanuelli, of the Vatican Observatory, brought a volume out in 1929. Mr. John Ohlsson has just published more extensive tables in the Annals of Lund Observatory, No. 3; they go to every degree of Right Ascension and declination, and give the galactic co-ordinates and the parallactic angle to hundredths of a degree. For economy of printing the tables are limited to half the sphere; the results for the other half are obtainable by adding 180° to longitude and changing the sign of the latitude. The galactic pole is assumed to be in R.A. 12^h40^m, N.Decl.28° (1900). The zero of galactic longitude is taken as the intersection of the galactic plane with the equator of 1900. This is convenient for astronomers of the present day, but will cease to be so in the course of centuries; for this reason the International Astronomical Union, at the Leyden meeting in 1928, recommended reckoning from the star Alpha Cygni, which is very close to the galactic plane, and has a very small proper motion. However, it is easy to pass from one zero point to another; it merely requires the addition of a constant to the longitude. The constants required to reduce to several suggested zero points are given in the introduction.

In using the tables all Right Ascensions and declinations must be reduced to the equinox of 1900 before entering them. Since some workers may prefer to use another position of the galactic pole, formulæ of reduction are given to facilitate such a transformation. Since galactic co-ordinates to rough fractions of a degree are sufficiently exact for many purposes, a large diagram is published in the volume in which the circles for every ten degrees of each co-ordinate of equatorial and galactic systems are inserted, one set in continuous lines, the other in broken ones; resulting positions can be read off at sight. If a position comes near the edge of the diagram, it is more convenient to work with the antipodal position.

Recent Discoveries in Mexico and Guatemala

EXCAVATIONS on Monte Alban in the State of Oaxaca, Mexico, the site on which the rich grave treasure of gold and other ornaments was found in January of last year, were resumed at the end of October by Señor Alfonso Caso on an extended scale immediately the decision of the Supreme Court on the question of State jurisdiction over antiquities had been made known. By the end of November, according to progress reports for which we are indebted to Science Service (Washington, D.C.), some interesting results had been achieved, although in certain respects their exact bearing at present remains obscure.

Among the more striking of the finds is a tomb remarkable for its small size. It is less than 2 ft. wide, and not 7 ft. in length. It is lined with stone, and the door was closed with a corn-grinding stone. Immediately within the doorway was a headless skeleton; while at the back part of the tomb were a heap of human bones, four large dishes and animal bones. In addition, it contained two incense burners, two greenstone axes, jade, and a bird's skull. The most noteworthy feature of the discovery, however, is that on the front of the tomb, underneath the lintel and on the door jambs, as well as on the stone floor at the entrance, are paintings in red, green and yellow. If the culture is Zapotec, these are the first Zapotecan paintings to be recorded. It is concluded that they deal with the calendar, representing year- and day-names in the Mayan or Zapotecan calendar.

Outside the tomb were found a number of objects in pottery which have all the appearance of votive offerings—objects resembling ears of corn, human hands, a tiger's foot, etc., with the image of a corn god and another deity not identified.

Another find of a singular character is a series of human figures in eccentric postures. These were found as a border or frieze at the base of a stepped pyramid, or temple, which is now being excavated. This is known as the 'Temple of the Dancers' from figures on the walls of a stone-lined tunnel in the mound, which was penetrated a few years ago. Of the figures which have now been brought to light, some are shown as crawling or swimming, while others lie on their backs. One holds an object at his lips as if drinking. Others appear to be deformed. It is thought that the figures may represent a priestly orgiastic fertility rite such as was described by early Spanish writers. This view is supported by the emphasis laid on the sex of the figures—normally the priests were expected to be celibate.

A second tomb of almost identical dimensions, with a roof shaped as an inverted V, has been discovered. It contained parts of two skeletons with funerary furniture, possibly secondary interments.

It remains only to describe what is up to the present the most remarkable feature of the site, of which the purpose is at present obscure. This is a series of stone-lined tunnels too small to serve as emergency passages, as was at first suggested, and not apparently intended for drainage. The first was discovered at the close of last season's work, but its exploration left until this year. When it was entered on the resumption of work, it was found to be so small—20 in. high by 25 in. wide—that the explorers had to proceed stretched at full length on their backs and work their way along by elbows and toes. At a distance of 195 ft. in the tunnel a skeleton was found, accompanied by an incense burner, funerary urns and ornaments of jade, stone and turquoise as well as a few pearls. Some yards further the tunnel was found to be blocked and had to be entered again by a shaft sunk from the surface 25 ft. above for the purpose. A second skeleton was found 320 ft. from the entrance, just before the tunnel terminated at the side of the north terrace. It was found that a number of even smaller tunnels, not more than a foot high, led into the larger tunnel. Of these one had tiny steps leading down to it.

Two further tunnels of similar character to the first were found, but packed with earth or clay. Finally, a complex of miniature tunnels was found to the east of the famous treasure tomb. All are stone-lined and some are less than a foot high. Some, but not all, have the inverted V roof. The application of a smoke test revealed a number of unexpected exits.

The Carnegie Institution of Washington has now issued particulars of the important discovery of Mayan pottery made in 1931 at Uaxactun, Guatemala, by one of its expeditions (*News Service Bull.*, vol. 2, No. 36). This discovery was remarkable not only as an indication of the high standard attained in ceramics by the Maya at an early date, but also as the first example of a Maya date inscribed on any material other than stone or stucco.

The pottery was discovered in two burial vaults at the top of a pyramid in Group A in the so-called acropolis. This pyramid is the third in a series of five built one on top of the other in accordance with Maya practice.

Vault 1 is 7½ ft. long, 1¾ ft. wide and 2 ft. high, with walls of roughly-cut stone and six limestone slabs superimposed, as a cover. It contained the skeleton of an adult male with funerary furniture, offerings, ornaments, etc., among which was a remarkable polychrome vase. The second vault was approximately of the same size, though slightly shorter. It contained the remains of several skeletons and seven polychrome vases. Between the two vaults were two more polychrome bowls which had probably accompanied a secondary burial.

Of the polychrome vessels, which are painted in red, orange and black, all are sufficiently noteworthy; but three in particular stand out. A shallow bowl 14 in. in diameter, a flanged tripod dish and the cylindrical jar found in the first vault. All are painted with representations of one or more human figures. The most elaborate shows among other figures a naked man hanging head downward with two jaguars apparently about to spring on him. He is evidently the victim of a human sacrifice. The design is divided into two fields by the figure of a serpent across the vessel. The scene shown on the cylindrical jar is complicated; but it is thought to represent the reception of a deputation or embassy by a dignitary who is seated on a dais. The date, to which reference is made above, is shown in sixteen calendrical glyphs which have been interpreted by Dr. S. P. Morley, after a slight emendation, as giving the date 120 B.C. or A.D. 140 according to the chronological system employed in interpretation. This, however, is not the date of the vase; the painting is taken to be a record of an event long past.

Band Spectra of Diatomic Molecules*

DURING the last ten years, few branches of physical inquiry have called forth a greater output of published work than that of molecular spectra. Many reasons may doubtless be adduced to account for this. On the theoretical side, it is generally recognised that the anharmonic vibrating-rotating molecule with its complex magnetic couplings, and the interaction of these energy types with each other and with the electronic energy, provides one of the most fascinating applications of the quantum theory. On the experimental side, æsthetic considerations (and the interest of unravelling and ordering what is often a very complex system of spectral lines) must be given no little weight. Whatever may be the impressions given by a reading of the theory, the experimentalist is well aware that scarcely any band system is really typical or without peculiarities of particular significance for the structure of the emitting molecule.

Further reasons are found also in the variety of other fields of physical inquiry with which this subject has become closely related. The determination of the heats of dissociation of molecules from their spectral data is a well known possibility. The method is applicable to molecular ions and other diatomic molecules incapable of direct thermo-chemical investigation. In another field—that of isotopy—the discovery and quantitative estimation of comparatively rare isotopes of several common elements are well known. The prolific output of work on the spectrum of light scattered by molecules—the Raman effect—has among other things provided a new weapon for studying the solid and liquid states and the vibrations of complex molecular groupings. Molecular spectra have also made a definite contribution to astrophysical knowledge, while photochemical investigation stands clearly in a very close relationship to the subject. The nature of valency and of related topics, which has been clarified in recent years by the work of Heitler, London, and others, provides another link with chemistry.

For a subject with such wide associations, the collected literature has been remarkably scanty, even when we make due allowance for the difficulty of providing it during a period of rapid development. The present writer, faced with the problem of advising men wishing to undertake post-graduate research in this subject as to their reading, has found the answer one of perennial difficulty. The advice given has usually been: "Read certain sections of the National Research Council Bulletin on 'Molecular Spectra' and afterwards follow the original papers of some leading worker in this field, tracing the development of his thought in recent years". With the publication of the eminently readable report by the Physical Society referred to below, this difficulty should be resolved for many years.

Dr. W. Jevons is to be congratulated on the completion of a valuable piece of work. He has produced a model report, subsuming on the part of the general reader no previous specialised knowledge of the subject and yet providing for the expert a most useful compilation of data. Within the limits which Dr. Jevons has prescribed for himself, he has written a clear and well arranged account of the subject for which physicists and chemists alike will wish to thank him; research workers will do so more especially for the valuable appendices he has included. Through the tables and classified bibliography given here there is now provided a rapid and reliable approach to the literature of almost all known band spectra of diatomic molecules.

R. C. JOHNSON.

International Auxiliary Languages*

IN the pamphlets referred to below, Dr. Ritter gives us an excellent survey, with statistics, of the language situation of the world, and of the cogent reasons in favour of the adoption, by formal agreement, of some easily learned international language.

The complacent assurance, once almost universal, that the 'blessings' of industrial civilisation, and of 'English, well and clearly spoken', would rapidly extend to the whole of humanity, has given place to a sceptical attitude towards our own culture. A powerful reverse current has set in; many of our own eminent thinkers set the highest value upon a multitude of cultures, upon competition rather than fusion between them, even upon war itself. Innumerable students all over the world are being educated in languages, sometimes limited to one or two millions of people, which give them no access to English, French, and German literature. Those who are very good natural linguists may acquire all three of these, but the majority will acquire only one, and many, ungifted as linguists, will never read easily in any but their mother tongue. A point worthy of strong emphasis is the fact that inability to acquire foreign languages is in no way a sign of mental inferiority generally.

Dr. Ritter points out that the above facts limit the field of selection for persons who are to assist in international co-operation, as in the League of Nations. It is obvious that discussions carried on through interpreters are severely handicapped. The same argument applies, of course, over much wider fields. Dr. Ritter pleads for the formation by the League of a commission to study the problem, and hopes for the endowment out of private funds of an institute as well. He also puts forward his own suggestions for a world language; a phonetic, orthographic, and grammatical simplification of Mr. Ogden's "Basic English". It is much altered, but readily intelligible to an English reader, as soon as the rules of simplification are grasped. It is somehow less of a shock than the efforts of our own more advanced spelling reformers, or Prof. Zacharisson's "Anglic". Those whose hearts are set upon the retention of stylistic elegancies, even in the statement of pure matters of fact, will not like it any better than Mr. Ogden's "Basic".

---

* "Die Sprache im internationalen Verkehr" (2nd ed., pp. 48) and "Die Weltverkehrssprache" (pp. 12), by Dr. Erwin Ritter, of the International Labour Bureau, Geneva. Printed as MS., 1932.

Dr. Ritter is concerned solely with the necessity for an officially recognised international language. He believes that no living language stands a chance of adoption owing to jealousy, and also to more realistic considerations of commercial competition. Further progress along the lines of Esperanto and Ido seems unlikely; all the signs point to Basic English competing with them successfully on account of its superior simplicity and practicality, wherever these qualities are called for. Also, the fact that to learn it is to make a good beginning with learning standard English tells enormously in its favour. Dr. Ritter's language (he has not named it) is somewhat easier to learn, since it has only 17 letters, three pronouns, and no irregularities; but learning it means learning English wrongly, and that will operate against it. But Dr. Ritter believes that only so, as an invented language, would it stand a chance of adoption by the League.

Edison's first invention was an electric vote recorder for Congress, designed to expedite business. It was gently but firmly explained to him that this is the last thing in the world that politicians desire.

H. S. H.

New Applications of the Cathode Ray Oscillograph

THE modern cathode ray oscillograph has now become a well-established tool of the physicist and electrical engineer for the experimental study of electromotive forces varying with time. In addition to its normal oscillographic use for the investigation of the wave-form of periodic electromotive forces, it has been extensively used for the study of transient or non-recurring phenomena, such as, for example, the reception of an atmospheric in a wireless aerial.

The electromotive force which operates the oscillograph may not, however, be the ultimate object of study; this force may be produced or derived in some manner from the phenomena which it is desired to investigate. It is well-known that certain reactions taking place in the human body, such as the beating of the heart, may be made to produce changes in the flow of current in an electrical circuit connected to the body in a suitable manner. The vibrating string galvanometer has been used extensively for this purpose in the past. It is quite probable, however, that the cathode ray oscillograph will find a useful application in this field shortly, since it has an advantage over the galvanometer in that it provides a continuously visible image of the derived electrical variations and the results of various experimental operations may be seen immediately on the oscillograph screen.

One of the difficulties accompanying the use of the cathode ray oscillograph in the past has been that of providing a suitable time-base for the spot of light forming the image on the fluorescent screen. In the June 1932 issue of the *Journal of the Institution of Electrical Engineers*, a description is given of a method of producing a circular time base as developed by the staff of the Radio Research Station, Slough. In this method, sine wave alternating voltages are applied in phase quadrature to the deflecting plates of the cathode ray oscillograph, with the result that a circular motion is imparted to the spot on the screen, the time of rotation of the spot being equal to the period of the alternating current supply. The electromotive force to be studied is introduced at a suitable point in the circuit and produces radial deflections of the spot from its circular path, without affecting the intensity or definition of the image. The time of recurrence or duration of the phenomenon under observation can be estimated from angular measurements on the screen, while the amplitude of the electromotive force is measured radially.

The paper referred to above mentions the possible application of the method to the comparison of high-order harmonic frequencies, and to the checking of the period of a seconds pendulum against an alternating current supply of accurately controlled frequency. In the latter case a rate of the pendulum corresponding to about 2½ seconds a day can be determined in a few seconds, while any departure from uniformity of the pendulum swing may be quickly studied.

Heavy Current Circuit-Breakers

IN most countries of the world the supply of towns and industrial districts with electrical energy is a matter of the greatest importance. The increasing size of central power stations and the extensive interconnexion of high tension networks, which in some cases spreads over the political frontiers of individual countries, makes the proper choice of protective apparatus essential to the safety of the system. One of the most troublesome faults arises when there is a short circuit in some part of the network. To counteract its effects apparatus to break the circuit, 'circuit-breakers', must be used in connexion with suitable relays. These must be capable of opening and closing on a short circuit several times consecutively without danger.

In the *Brown Boveri Review* for June last, H. Thommen describes the plant used in the Brown Boveri works in Baden for testing circuit-breakers. Prior to 1897, knife-switches with air-breaks were employed to break the circuit, but they were unsuitable as they produced very long arcs even at low pressures. C. E. L. Brown was the first to break the arc under oil and it was thought that this would give the perfect solution. It was found when breaking high power that oil circuit-breakers occasionally gave rise to serious disturbances. Sometimes the mechanical strength proved insufficient, or the opening distance of the contacts was too small so that flash overs to the casing resulted. Unsuitable contacts on heavy currents sometimes welded together and ruined the apparatus.

The very thorough tests carried out by the Brown Boveri Co. have cleared up many of the difficulties which lay in the way of designers. By means of slow-motion cinematography, they demonstrated the oil piston theory. According to this theory, rapidly growing bubbles form around the arc at rupture in the oil. The oil above the break is projected like a piston against the cover. When this happens a high pressure is rapidly developed and the current is broken. The total amount of gas produced depends on the energy dissipated in the arc and formulæ to determine this energy are given.

Recently there has been a revival of interest in water circuit-breakers. They have the advantage of not using an inflammable liquid but they do not eliminate the danger of explosion, since if the arc is not broken quickly enough, steam is produced in such quantities that the breaker blows up.

The compressed air breaker works satisfactorily as the pressure does not exceed a definite value, but a compressed air plant is necessary to operate it. Breakers without oil based on the principle of the action of a magnetic field on the arc have many advantages but on account of difficulties in insulation they cannot be used in practice with high voltages. Oscillograms are shown of how the current varies when different kinds of experimental breakers are in action.

Climate of Hong-Kong

"THE Climate of Hong-Kong", by T. F. Claxton, published by the Royal Observatory, Hong-Kong, as an appendix to the ordinary annual summary of Hong-Kong observations for 1931, is one of the most complete accounts of the climate of a station in the Far East. It summarises and discusses the observations made from 1884 to 1929. Most of the tables are in the form in which the mean value of a meteorological element, for example, atmospheric pressure, temperature, etc., for each hour is shown for each calendar month, the minimum hourly value of each element being taken as zero while the other values are expressed as departures therefrom in the customary units. A collection of tables of this kind makes a very indigestible meal for all except the expert meteorologist and for this reason the explanatory discussion is very welcome, particularly the general discussion of the seasons.

The seasonal rhythm in Hong-Kong is, of course, greatly influenced by the Asiatic monsoon. Lying practically on the Tropic of Cancer, the north-east monsoon in the winter does not give rise to much cold weather; a minimum temperature of 45° is reckoned a low one, while an afternoon maximum of 75°, for which in England one sometimes must wait until nearly the middle of the summer, is not rare in January. Mist and fog are of common occurrence in the period of rapidly rising temperature around March, generally when pressure is falling over China and the north-east monsoon is weakening; much of it is due to dynamical cooling of advancing damp southerly winds. The summer, with its mean temperature of 82° F., is characterised by unsteady winds, rather frequent thunder storms and heavy rain; the destructive effects of a typhoon are occasionally felt, more especially in late August. October brings back the north-east monsoon, and, generally, fine dry weather leading back through a quickly falling temperature to the winter.

There is a considerable section devoted to the discussion of typhoons, containing a number of important statistical tables, and the non-tabular part of the work ends with an interesting item seldom to be found in works of this kind—an account of the principal empirical rules of weather forecasting for the region under discussion.

University and Educational Intelligence

LONDON.—The Clothworkers' Company, the Grocers' Company, the Drapers' Company and the Skinners' Company has each decided to make very generous grants to the University in the shape of annual payments extending over a series of years. These grants will amount in all to £20,000 from the Clothworkers' Company, £10,000 from the Grocers' Company, £5,000 from the Drapers' Company, to whose munificent help for East London College the University is already greatly indebted, and £5,000 from the Skinners' Company. As in the case of the grants already announced from the Corporation of the City of London, from the Mercers' Company and from the Fishmongers' Company, these benefactions will be applied towards meeting the cost of the new Ceremonial Hall to be erected on the University's site in Bloomsbury.

A COURSE of ten lectures on alternating currents and electrical oscillations will be given by Dr. D. Owen, head of the Department of Physics and Mathematics of the Sir John Cass Technical Institute, at the Institute, Jewry Street, Aldgate, London, E.C.3, on Tuesday evenings commencing on January 31. The lectures will be accompanied by practical demonstrations. Further information can be obtained from Dr. Owen at the Institute.

THE school magazine coming from Stowe School, entitled the *Stoic*, is a sumptuously printed and illustrated record of extra-curricular activities among which film exhibitions have an important place. The school was one of the first to have a full-size silent projector and to change over to sound. Its recently founded Film Society aims at contributing towards the development of the art of the cinema by helping to prepare (in the words of the headmaster's inaugural speech) a forward-looking and active-minded public waiting to welcome the work of exploration through this medium of undiscovered territory of the mind. It is worthy of note that, in the list of films exhibited during last term, there are none of the professedly instructional type.

STATISTICS of secondary schools in the United States, published in a recent bulletin of the Office of Education, Washington, show an aggregate enrolment in 1930 of more than five million—roughly half of the population of secondary school age. The schools tend to increase in size, the average enrolment having increased from 211 in 1926 to 234 in 1930. Five per cent of them had, in the latter year, more than 1,000 pupils; 27 in New York and Chicago had more than 5,000, the largest of all having more than 10,000 pupils. Re-organisations, involving the incorporation in the secondary school scheme of some of the years previously covered by elementary school courses, have made considerable headway in recent years, especially in schools with from 300 to 2,500 pupils, two-thirds of which have now been re-organised. The proportion of men to women teachers in secondary schools, except in those for negroes, shows a tendency to increase. School libraries have increased in size steadily; the average number of volumes has risen from 1,652 in 1926 to 2,000 in 1930.

Calendar of Nature Topics

Tempora mutantur

1859, January 21.—The celebrated Eland dinner was held at the London Tavern, Prof. Owen in the chair. This dinner set on foot a movement for the acclimatisation of foreign animals, and the following year an Acclimatisation Society was formed with F. T. Buckland as organising secretary. By this time the Paris Société d'Acclimatation was in active operation. In 1857 it had offered a series of prizes "for the introduction into France, and her colonies, of various beasts, birds, fish, insects and plants". (Buckland's Life.)

1932—"Destructive Imported Animals Act," passed by the Parliament of Great Britain and Northern Ireland, placing restrictions upon the importation of foreign animals.

Skylark's First Song of the Year

Few naturalists' calendars fail to record the first singing of the skylark (*Alauda arvensis*) and most place it in the latter half of January or early days of February. At Selborne, Gilbert White heard it on January 21, and about the same period Markwick, at Catsfield in Sussex, places his earliest record on January 12 and his latest on February 27. Half a century later Leonard Blomefield (or Jenyns) gives his first record, at Swaffham Bulbeck in Cambridgeshire, as January 7, his latest as February 21, and the mean of his seventeen years' observations (1820–31, 1845–49) places the first singing on January 22. On the other hand, a twelve years' average in recent years, from data in the annual Phenological Report of the Royal Meteorological Society, fixes the date at February 11. Is the skylark really beginning its song season later in the new year than it used to begin ?

Duration of the Skylark's Song

There is a tendency to exaggerate the duration of the skylark's song ; a quarter of an hour is a common estimate, half an hour has been recorded, and an hour has been suggested as the maximum duration. But an accurate timing of more than a thousand songs, not reckoning those which failed to last half a minute, reveals a standard quite different. During three years, Noble Rollin timed morning songs in a particular locality (on the outskirts of South Shields) and found that the average duration of 549 songs was but 2·22 minutes. The yearly averages were remarkably consistent : 1927, 2·19 minutes ; 1928, 2·30 ; 1929, 2·20 (*Scot. Nat.*, 1931, pp. 47–54). Naturally, the song is not equally long throughout the year. It falls into two distinct periods, a spring period beginning in January or February, reaching a climax in May and June (average 2·7 minutes) and ending in the silence of August, and an autumn period beginning lustily in September (average slightly exceeding 3 minutes) and ceasing in November. A curious fall in the average length of the song which occurs in April, is suggested by Rollin to be possibly due to the late beginning of the younger birds, and their less practised singing ; but it is noteworthy that all the songs of 8 minutes and more fall within the spring or breeding period. The length of the song seems to be an individual characteristic, for the times of two special birds were found to be fairly consistent, all the recorded songs of one lasting, in minutes, 19, 17, 16, 29, 12, and of the other, 10½, 10¼, 19½, 1, 6. Moreover, it was noticed that the long singers kept together in one field, the short singers in another ; and since there is no suggestion of a selected chorus amongst skylarks, this curious fact seems to point to length of song being, in part at any rate, a function of age and practice, and to imply a certain amount of age segregation, the older and more practised larks separating into a colony distinct from the younger and less practised.

Arctic Ice passes Cape Farewell

January 25.—In the Arctic Ocean there is an almost continuous drift of ice from the sea north of Bering Strait towards the north of Greenland. During the winter, this floating ice-cap is firmly frozen, but in summer it breaks up, especially on the edges, and large masses of drift ice enter the ocean between Spitsbergen and Greenland, whence the East Greenland Current carries them southwards. The first ice-floes pass Angmagsalik in East Greenland about November 6, and reach Cape Farewell early in the following year, the average date being January 25. Rounding Cape Farewell, they travel northwards along the west coast of Greenland, reaching Godthaab early in May, after which the ice-masses decrease under the influence of summer melting. These remarkable movements of the arctic ice have important effects on the weather of the northern parts of the North Atlantic Ocean, as well as on the seal fisheries and the navigability of the northern seas.

Metamorphosis of *Calanus*

The small copepod crustacean *Calanus finmarchicus*, the numbers of which make it an important food supply of many marine organisms and so a link in the conversion of inorganic matter in the sea into human food, is now entering the last of its many stages. During January and sometimes even in the last days of December, it moults its final juvenile coat and becomes an adult, at any rate in the Firth of Clyde, for the change is not synchronous in different areas. This is the last of a series of twelve stages of development, six larval nauplius stages and five post-larval copepodid stages preceding the adult stage, and each stage leads to the next by way of a moult. The survivors of the hordes of the previous summer live through the autumn and winter, from September or October onwards, in the final copepodid stage, Stage 5 ; their development seems to be checked, only to be resumed with the January moult. During this month males predominate in the catches, but in February and thereafter females are more numerous, and this is true not only for the Firth of Clyde, but also in the English Channel, off the west coast of Ireland, and off the Norwegian coast.

What is the stimulus which breaks the autumn-winter condition and induces more rapid development and the final moult ? The scientific workers at Millport Marine Station have tested temperature. If the autumn stages are kept in the laboratory instead of the open sea, they moult in about three weeks. Low temperature definitely retards moulting ; but since the sea keeps getting colder until March, rising temperature can scarcely be the natural stimulus. Similarly light and food have been tested but neither seems to hasten the final moult ; there is no definite change in the sea that they know of which would provide the wanted stimulus.

Societies and Academies

Dublin

Royal Irish Academy, Dec. 12. J. J. Nolan and J. G. O'Keeffe: Multiply-charged large ions. Atmospheric condensation nuclei can be charged up so as to carry several thousand electronic charges. The mobilities appear to be unaltered. Spray ions have charges of the order of a hundred electrons. The existence of definite mobility groups for these ions is again demonstrated. R. W. Ditchburn: (1) *The frequency distribution of resonance radiation.* This paper discusses the frequency distribution of light emitted by an atom excited by the absorption of radiation the frequency of which is not exactly equal to the atomic resonance frequency. A recent experiment by Korff (*Phys. Rev.*, 41, 538; 1932) is criticised and it is suggested that this type of experiment cannot give any information on this question. (2) *The possibility of separating isotopes by the use of resonance radiation.* Photochemical reactions involving the use of resonance radiation are suggested.

Paris

Academy of Sciences, Nov. 28 (vol. 195, pp. 985–1048). Ch. Maurain and J. Devaux: Study on the total calorific radiation in Greenland. The solar radiation in the polar regions is relatively considerable. Comparisons are made with the corresponding figures obtained at the Parc Saint-Maur Observatory, near Paris. Emile Cotton: The non-rotational movement of a liquid limited by mobile, indeformable walls. Aymar de la Baume Pluvinel was elected a member of the Section of Astronomy in succession to the late G. Bigourdan. N. Botea: *Some partial differential equations.* C. Desaint: The transformation of the $(p+q)$th species for the domains of existence. Julius Wolff and Bastian Grootenboer. A property of a derivative of a function with a real positive part. D. Riabouchinsky: The hydraulic analogue of the movements of a compressible fluid.—L. Goldstein: The conservation of momentum in electron collisions.—Vaclav Bubenik: *The theory of electric filters.* W. Kemula and St. Mrazek: Measurements of the absorption of ultra-violet rays by methane, ethane and normal butane in the gaseous condition. Measurements were made of the absorption between the wave-lengths 6000 A. and 1965 A. Within this range, no radiation is absorbed by the three pure gases. A. Witt: *Starting oscillations of very high frequency.* P. Donzelot and J. Divoux: A method of compensating plate currents. Instead of the usual compensation making use of accumulators, to compensate the normal plate current of a valve, use is made of an identical valve, the same high-tension battery feeding both valves. Greater stability can be obtained. Th. V. Ionescu and C. Mihul: Ionised gases in the magnetic field: pressures greater than 0·001 mm. of mercury. The results of experiments on hydrogen and nitrogen are given graphically, showing the conductivity as a function of the wave-length, magnetic field, and pressure.—J. Janin: The spark spectrum of rubidium in the extreme ultra-violet. Papayanno: The influence of time on the conductivity of colloids measured at two different levels. E. Vellinger: The superficial affinity of caoutchouc for the loading. J. P. Mathieu: The compounds of tartaric acid and chromium. Chromium hydroxide dissolves in solutions of tartaric acid giving a normal tartrate *and this is transformed in solution into* a complex compound not giving the usual chromium reactions. This compound cannot be isolated in the crystalline state but its composition has been studied by physicochemical methods, acidity, conductivity, rotatory power and light absorption. These give it a formula of $H_2(TCr)$. Robert Berthon: The heats of moistening silica gel with various liquids. The experimental results are not in agreement with the hypothesis of Patrick and Grimm. Any purely thermodynamic theory of the heat of moistening of silica gel is incomplete because it neglects the geometric factors of the surface. Jean Galibourg: The influence of the value of the elongation realised in the course of successive extensions, followed by ageing, on the elastic limit and Young's modulus of a mild steel. André Kling and Alfred Soulier: The accidental ignition of vapours of petrols by electric sparks. The author considers that sparks produced by the friction of insulated bodies, such as pulleys in motion, are incapable of igniting mixtures of air and petrol. Pierre Jolibois and Louis Cloutier: The existence of basic phosphates. The existence of basic phosphates prepared in the wet way is doubtful. W. S. Reich: *Glycogen triacetate.* Under the conditions laid down, it is possible to acetylate glycogen, forming the triacetate and regenerate glycogen identical in all respects with the original glycogen. Jacques Bourcart: The marine Pliocene of Morocco. An attempt at the history of the Moroccan Atlantic. P. Geoffroy: Contributions to the geological study of the neighbourhood of Oran (Algeria). Paul Guérin: Hydrocyanic acid in *Glyceria aquatica.* With the exception of the fruit, all the organs of *Glyceria aquatica* give hydrocyanic acid, the young leaves and the flowers showing the highest proportion. Henri Coupin: The determinism of the formation of sporangia and zygospores in *Sporodinia grandis.* Pierre Gavaudan: Some observations concerning the physical structure of the cytoplasm of a hemi-ascomycete fungus, *Ascoidea rubescens.* Mlle. Dzung Tsing Wang: Cytological observations on *Ustilago hordei.* Charles Pérez: Differential characters of the sexes in hermit crabs of the genus *Diogenes.* André Bonot: The modification of the seric proteins isolated by the acetone method and myxoprotein. A criticism of the acetone method of Piettre and Vila. The author does not regard the fraction isolated and studied by Piettre, Achard and Arcand under the name of myxoprotein as a definite homogeneous fraction.

Melbourne

Royal Society of Victoria, Nov. 10. Elizabeth A. Ripper: The stromatoporoids of the Lilydale limestone. (1) *Actinostroma* and *Clathrodictyon.* The Silurian (Yoringian) limestone of Lilydale, Victoria, contains a rich stromatoporoid fauna. Four new species and one subspecies are described. *Actinostroma compactum* is closely related to *A. clathratum* Nich. of the British and German Devonian; *A. altum* to the Wenlock form *A. intertextum* Nich., while *A. verrucosum*, Goldfuss, is a typically Middle Devonian species. The species of *Clathrodictyon* are related to Silurian forms: *C. regulare cylindriferum* differs only from the European form *C. regulare*, Rosen, in the possession of astrorhizal cylinders; *C. calamosum* is of the type of *C. striatellum*, d'Orbigny, while *C. chapmani* is apparently distinct from all other species of

Clathrodictyon. **Jean Heyward**: Two species of *Ophiocytium Nageli* in Victoria, *O. terrestris* n.s. and *O. arbuscula* Rabenhorst. Two further species of *Ophiocytium Nageli* are recorded for Victoria. One, which was isolated from the soil, proved to be a new species and was named *Ophiocytium terrestris.* This is the first record of this genus from the soil. The second species, *Ophiocytium arbuscula* Rabenhorst, was found in a pool at Royal Park, Melbourne, attached to filaments of *Œdogonium* species. **Eileen E. Fisher**: The 'sooty moulds' of some Australian plants. Fungal forms have been isolated from 'sooty moulds' occurring naturally on the following hosts—*Bursaria spinosa, Leptospermum scoparium, L. lævigatum, Myoporum insulare, Melaleuca* sp. The composite character of the 'sooty moulds' is demonstrated. *Caphodium walteri* Sacc. on *Bursaria spinosa* has been shown by direct observation and cultural work to be *Teichospora salicina,* Mont., Gau. and demonstrates the cosmopolitan distribution of the type form of the genus. *Capnodium citricolum* McAlp, is synonymous with *Teichospora salicina. Teichospora australe* (Mont.) Arnaud is recorded on *Leptospermum scoparium,* as the common perfect form found on this host. *Teichospora australe* has been recorded previously on conifers in Australia, and the same fungus appears in the unpublished records of the Mycological Herbarium, Department of Agriculture, Victoria, under the name *Limacinia melaleucas* (nomen nudum) on 'tea-tree'. *Limacinia fuliginodes* is recorded on *Melaleuca* species and is the first record of this fungus for Australia.

ROME

Royal National Academy of the Lincei: Communications received during the vacation. **Q. Majorana**: Further results of a new photoelectric experiment. As regards the increased electrical resistance exhibited by certain thin metal foil under the influence of intense pulsating radiation, different metals show markedly varying behaviour. Silver displays characteristic sensitivity towards ultra-violet rays, but aluminium and possibly zinc also are insensitive to such rays. With other radiations the various metals examined exhibit the effect in greater or less degree.—**E. Fermi**: Oscillation and rotation bands of ammonia. **N. Parravano** and **O. D'Agostino**: Velocity of dissolution of industrial aluminas in fused cryolite. Three samples of alumina, prepared in different ways, were found to vary in the rate at which they dissolved in molten cryolite. **G. Rovereto**: A tectonic interpretation of the western promontory of the Gulf of Spezia. **M. Ghermanesco**: Orthogonal polynomials with two variables. Based on the property of orthogonality, a systematic theory of these polynomials is projected. The first results obtained are here detailed. **Hans Hamburger**: Ribaucour's transformation and spherical representation (2): applications of the transformation to spherical representation. **V. Hlavatý**: Further results on the differential projective invariants of a curve in the projective space P_{n-1} ($n =$ or > 3). **L. Labocchetta**: The effective integration of discontinuous functions (3): periodic functions. **Maria Pastori**: Conjugated hemisymmetric tensors. **E. Volterra**: 'Linked' elasticity and its mathematical representation. A new method of studying the deformations of elastic solids is developed which appears to be of practical value, as it allows various problems in elastic statics to be solved in a systematic and simple manner. **M. Cimino**: The Einsteinian correction of time in a planetary motion. Utilising the principle of equivalence of Levi-Civita previously applied, the author deduces a law of cosmic time and the anomalistic and sidereal periods of revolution for an Einsteinian motion in ordinary Euclidean space. **M. Kiveliovitch**: Regularisation of two body impacts for forces inversely proportional to any power of the distance. **E. Martin**: Method (2) for calculating the orbit of a visual binary. **A. Proviero**: Further considerations on the extinction of seismographs. **E. Guerrieri**: Periodicity in the progressive course of the rainfall at Capodimonte during 1833–1931. The data given reveal a distinct periodicity of fifteen years in the rainfall. The mean duration of the change from a maximum to the next minimum is 9·33 years and that of the succeeding rise to a maximum, 6·00 years. **M. Baccaredda**: The structure of sphero-cobaltite. **A. Baroni**: Diselenomesoxanilides and oxyselenanilides. When treated with selenium monochloride, malonanilide yields diselenomesoxanilide, M.P. 209°–210°, and malono-*p*-toluidine, diselenomesoxi-*p*-toluidine, M.P. 211°. Oxyselenanilide, B.P. 111° at 26 mm. pressure, and oxyseleno-*o*-toluidine, B.P. 130° at 26 mm., are obtained by the action of selenium oxychloride on aniline and *o*-toluidine respectively. When heated with aniline or diphenylamine in presence of zinc chloride, these two compounds yield greenish-blue dyes and thus behave similarly to the thionylamines. **G. Charrier** and **Elisa Ghigi**: (1) Action of alkylmagnesium iodides on (1: 9)–benzanthrono–(10). The action of magnesium methyl iodide on anthraquinone or anthrone or one of their homologues gives rise to the corresponding carbinols, but, under similar treatment, benzanthrone yields, not the methylcarbinol, but 4–methylbenzanthrone and 10–methylene–3:4–dihydrobenzanthrene; the latter readily loses two atoms of hydrogen, to form 10–methylenebenzanthrene. From magnesium ethyl iodide and benzanthrone, only 4–ethylbenzanthrone could be obtained. (2) Action of ammonia on acenaphthenequinone. This action yields acenaphthazine and naphthalimide, and other orthoquinones give analogous products. **G. Natta** and **R. Pirani**: Solid solutions by precipitation, and isomorphism between complexes of platinum and of quadrivalent tellurium (2): Examination of cæsium chlorotellurite and of the systems, $CsPtCl_6-CsTeCl_6$ and $Rb_2PtCl_6-Cs_2PtCl_6$. Strict isomorphism exists between cæsium chlorotellurite and the chloroplatinates of cæsium and rubidium. The precipitation method of preparing solid solutions appears to be of general applicability. **E. Parisi** and **G. De Vito**: Distribution of nitrates and 'organisation' of nitrogen in the leaves of green plants. While the laminæ of the sunflower are comparatively poor in nitrates, the petioles and veins are rich in these salts and often contain more than any other organ, even than the root. It is, therefore, probable that the nitric acid undergoes organisation on passing into the lamina. This conclusion is supported by the results of analysis of leaves of wheat and beet. Both the laminæ and the petioles contain more amino nitrogen in the afternoon than in the early hours of the morning, so that, in the green parts of the plant at least, sunlight exerts an appreciable influence on the formation of amino compounds. **V. Famiani**: The nutritive value of wheat embryos. Addition of wheat embryos to the diet of rats fed on wheat alone—which limited their growth and greatly lowered their powers of resistance—produces some improvement in growth and resistance, and the further addition of a saline mixture renders growth and reproduction almost normal. V. Zagami: Nutrition with leguminous seeds, and reproduction. A diet of leguminous seeds inhibits the reproductive functions owing, not to any specific effect on the genital apparatus, but to retardation of the general development of the organism. This effect is due mainly to deficiency of mineral salts and, to a less extent, to lack of the lipo-soluble factors A and D.

Forthcoming Events

Saturday, Jan. 21

British Mycological Society, at 11—(at the Botanical Department, University College, Gower Street, W.C.1). Symposium and Discussion on "The Measurement of Disease Intensity".

Monday, Jan. 23

University of Leeds, at 5.15.—Prof. A. H. Sturtevant: "The Determination of Sex in Animals".

Royal Society of Arts, at 8—(Howard Lectures).—Dr. Ezer Griffiths: "Thermal Insulation" (succeeding lectures on Jan. 30 and Feb. 6).

Royal Geographical Society, at 8.30.—Capt. G. N. Humphreys: "Climbs and Flights in the Ruwenzori Range".

Tuesday, Jan. 24

University College, London, at 5.30.—F. J. Richards: "An Introduction to Indian Archæology" (succeeding lectures on Jan. 31, Feb. 7 and 14).

Wednesday, Jan. 25

Royal Astronomical Society, at 5.30.—(Joint Meeting with the Geological Society).—Discussion on "The Development of Fractures in the Earth's Crust".

Institution of Chemical Engineers, at 5.30.—"Sewage Disposal". Papers to be read by H. C. Whitehead and F. R. O'Shaughnessy, L. R. Howson, and Dr. Karl Imhoff.

Institution of Mining Engineers, at 11—(at the Institution of Mechanical Engineers, Storey's Gate, Westminster, London, S.W.1).—Annual General Meeting.

University College, London, at 5.30.—H. J. Helweg: "Popular Education in Denmark: The Folk High School" (succeeding lectures on Feb. 1 and 8).

Thursday, Jan. 26

Bedford College, London, at 5.15.—"Contemporary Developments in Science." Lord Rutherford: "The Transmutation of Matter".

University of London, at 5.30—(at St. Thomas's Hospital Medical School).—Prof. E. Mellanby: "Iodine and the Thyroid Gland" (succeeding lecture on Jan. 27).

Mineralogical Society, at 5.30.—Dr. L. J. Spencer: "Meteoric Irons and Silica-Glass from the Meteorite Craters of Henbury (Central Australia and Wabar (Arabia)".

Friday, Jan. 27

Chemical Society, at 6.—(Ostwald Memorial Lecture in the Chemistry Lecture Theatre, University of Liverpool). Prof. F. G. Donnan.

Royal Institution, at 9.—Sir Charles Peers: "The Ancient Monuments of England".

Saturday, Jan. 28

British Mycological Society, at 11—(at the Botanical Department, University College, Gower Street, W.C.1).—Symposium and Discussion on "The Measurement of Disease Intensity".

The Census of India, 1931[*]

THE Government of India showed both a commendable wisdom and a grasp of the realities of the situation in publishing an abstract of the main statistics of the census of 1931 while the Third Round Table Conference was still in session in London. The figures which are included in the abstract are of the greatest significance. Indeed, they are vital for an appreciation of the essence of the matters under discussion. By sheer weight of numbers, they bring out the magnitude of the problems involved in the proposed constitutional changes; and by indicating tendencies in the movements of population, they afford guidance in judging the possibility of permanence in an arrangement which aims at the form of democracy, but will depend for its working upon a delicate adjustment of the relations between different sections of the people.

The magnitude of the figures alone is stupendous. The destiny of more than three hundred and fifty millions of people is in the balance. The total population of India, as actually given, is 352,837,778, of whom 271,526,933, inhabitants of British India, are to receive the benefits and privileges of democratic institutions—the vast majority of them, however, for the present, in an attenuated form—and the remaining 81,310,845, natives of the Indian States, will be brought within the constitution of India under the scheme for federation.

The area of the Indian Empire, according to the latest estimate, is given as 1,808,679 square miles. This gives on the census figures of total population a mean density of 195 per square mile, the maximum being found in Cochin State, with a population of 814 to the square mile. In British India the most thickly populated area is Bengal, where there is a population of 646 to the square mile. The most sparsely populated areas in the Empire are Baluchistan with 5, and British Baluchistan with 9 to the square mile.

The statistics of total population, impressive as they are, must be taken in relation to the fact that they represent an increase in the ten years which have elapsed since the last census of 10·6 per cent. This rate of increase contrasts with an increase of 1·2 per cent in the previous decade, and has not been equalled since the period 1881–91; but there is no reason to suppose that with continuing improvements in sanitation and hygiene and the reduction, if not the elimination, of the incidence of famine and plague, a rate of increase substantially little lower will not be maintained, unless some unforeseen cause should introduce any serious modification in the conditions of life among the general run of the population.

---

[*] Census of India, 1931. Abstract of Tables giving the Main Statistics of the Census of the Indian Empire of 1931, with a Brief Introductory Note. Pp. 16+2 maps. (Calcutta: Government of India Central Publications Branch, 1932.) 9*d*.

Notwithstanding fluctuations in the decennial rate of increase, the growth of population since 1881 represents an increase of 39 per cent. A part of this, however, is due to the extension, from time to time, of the area brought under the operation of the census.

Enfranchisement, however gradually extended to a population of this size, would be an undertaking of sufficient magnitude in itself, especially among a population which speaks some 225 languages, exclusive of dialects, and ranges culturally from the level of a jungle tribe to those whose standard of civilisation may differ in kind, but does not differ materially in degree, from that of a member of an equivalent class in European society. In India, however, as must by now be generally appreciated, the initial difficulty is complicated by sharply marked divisions of race and creed which have given rise to the 'communal' problem. An electoral system, based on a territorial allocation of representatives, has to be adapted to represent justly different races and different creeds, each of which has its own social organisation and habits and, inevitably, its own distinctive and peculiar bias in political outlook arising therefrom. Even in the fairly homogeneous communities of the West, the problem of minorities has never been solved satisfactorily, although many attempts have been made. It has been said that the only right of a minority is that of turning itself into a majority. In India, if only the warmth of discussion and the wealth of argument were taken into account, it might not unreasonably be concluded that minorities alone had a claim to consideration.

This sensitiveness to the claim of minorities, abnormal as it would at one time have appeared to the average citizen of a European State, arises, it is seen, from a very real and irreconcilable incompatibility in thought, habit and religion between the different sections of Indian society, which, particularly as between Hindu and Moslem, at times flames out into acts of open hostility. The facts which the constitution will have to face are revealed in the tables of enumeration according to religions.

Taking the principal religions only, but omitting Buddhism which, practically, is confined to Burma, in all India there are :—Hindus, 239,195,140; Moslems, 77,677,545; Sikhs, 4,335,771; Tribal, 8,280,347; Christians, 6,292,763. In British India, the predominant factor is the relation between Hindus and Moslems; and within the ranks of the Hindus, the relation of the castes to the Exterior Castes, or, as they are more popularly known, the Depressed Classes. Here the figures are Hindus 177,727,988, of whom 40,254,576 are numbered among the Depressed Classes. The Moslems number 67,020,443; Christians, 3,866,660; Sikhs, 3,220,997; and Tribal, 5,779,709. More important than the totals, however, is their distribution and interrelation in the various provinces, upon which the question of representation has to be decided. In the fifteen provinces (including Burma and the Andamans) under which the figures are given, the Hindus are in the majority in ten, while the Moslems predominate in Bengal, the Punjab, Burma (not counting Buddhists), Baluchistan and the North-West Frontier Province. The Sikhs number 3,064,144 in the Punjab, exceed forty thousand in the North-West Frontier Province and the United Provinces of Agra and Oudh and are present in eleven other provinces in varying degree, the numbers, however, being relatively small.

Incidentally, it may be of interest to note the definition of Exterior Castes adopted for census purposes, which differs in certain respects from that of the Franchise Committee of the Round Table Conference. It includes all castes which are excluded from access to schools, wells, public bathing places, temples and in some cases burning ghats, which are refused for service as barbers, tailors or washermen, from whom water is not accepted, and who convey pollution by contact or proximity. The Depressed Classes had expectation of abolishing, by a declaration of equal rights to be incorporated in the constitution, the regulation or custom of exclusion from schools and other like places open to the higher castes, and other distinctions of inferiority.

The figures relating to the religious communities gain in significance when viewed proportionately, especially in their bearing on the political problem. In the decennial period, the increase in the Hindu population has been 10·4 per cent; but among the Moslems it has been 13 per cent; or, expressed in ratios per 1,000, the Hindus have fallen from 684 to 682, while the Moslems have risen from 217 to 222. This latter figure is the continuation of a steady increase which has been going on for the last half-century. The tribal figures also show a decrease in the decade—from 31 per thousand to 24, but this does not necessarily mean that the tribesmen are decreasing in numbers. It is probably to be accounted for in greater part as due to transference to the number of Hindus, in accordance with the process of Hinduising the tribal religions which has been in progress from time immemorial.

Among the remaining figures which may be regarded as having special significance in relation to the transitional phase through which India is now passing, are those giving the degree of literacy, the proportion of urban to rural population, and occupations.

The figures for literacy show a marked advance. The number per 1,000 aged five years and more who can read and write is 156 male and 29 female. In 1921 the corresponding figures were 122 male and 18 female. The number of literate females is now more than four millions, whereas thirty years ago they numbered less than a million. Among the Depressed Classes in British India, the percentage of literacy is 1·6.

The real India, it is always said, is the India of the rural population and the agricultural classes, although the urban population may be more in evidence and may thereby, in changed conditions, obtain more and more a preponderating voice in the affairs of the people. The urban population is undoubtedly growing and may be expected to increase more rapidly as India becomes industrialised and draws a proportion of the rural population to the towns, as it has already begun to do, for example, in Bombay. Since 1921 the increase in the urban population has been 0·9 per cent and it now numbers 11 per cent of the total. In occupations, agriculture accounts for 66·4 per cent of the working population. There is some doubt as to the exact numbers engaged in organised industry; but they are put at about 3,250,000 and at a maximum not exceeding 5,000,000, while the number employed in establishments governed by the Factory Acts is 1,553,169.

These, then, are the more significant of the figures which give the statistical side of the problems confronting those who have to frame a constitution for India. Their object is to adapt an essentially western institution to an eastern community, in which caste, the antithesis of democracy, prevails as the determining factor in the lives of the vast majority of the community and influences even the Moslem. It may, indeed, be regretted that the opportunity was not sought to develop native Indian institutions; but such regrets are unavailing. It is probable that the die was cast irrevocably in the days when Indian culture was despised and a university system was set up which was devised to throw open to India the way to development along western lines. Time and stress alone can prove the wisdom of the course that has been chosen.

The Spirit of Research

The Spirit of Research. By Dr. T. Brailsford Robertson. Edited by Jane W. Robertson. Pp. xiv + 210 + 2 plates. (Adelaide: F. W. Preece and Sons, 1931.) 8*s*. 6*d*. net.

BRAILSFORD ROBERTSON devoted a brief but intensive life to scientific research, during which he found time to write essays of a more general appeal, some of which are collected here in book form. Born in Edinburgh, he went at an early age to Adelaide, and after a period of thirteen years in California, returned there as professor of physiology in 1919, where he died in 1930. This book, which in a sense is a memorial volume, is an all-Australian production: we like to regard it as a symbol that the torch of scientific truth burns brightly under the Southern Cross.

Robertson was an enthusiast: he was fortunate to come early after graduation under the influence of another enthusiast, Jacques Loeb, with whom he worked, and later succeeded, at Berkeley, California. Both were sceptics of accepted doctrines, both were men of fearless independence and unbounded energy. It was Loeb's influence that caused Robertson to attack big problems rather than work in restricted fields, and encouraged him to undertake the problem of growth and senescence as his main life work.

It is the spirit of research that counts. Observations, comparison, deduction, trial are the factors which have established all we know from the days of such a primitive act as the production of fire to the latest hypothesis of the structure of the atom. Loeb used a simple shed on the sea shore with an equipment of the simplest and cheapest character for his experiments on the artificial parthenogenesis of sea-urchins, and yet obtained results which are among the most valuable in biology. The modern physicist requires the most complex and costly apparatus for his experiments on the smashing of the atom.

Since the War, research has been discovered to have a cash value and it has become popular alike with the Press, public and those persons who practise it as a means of livelihood. There are not wanting those critics who would avoid the use of the term 'research' for such work and prefer to call it investigation. At any rate, no one will deny that a cash reward is not in harmony with the true spirit of research. Precisely in the proportion that the worker devotes himself to research, so he must relinquish the desire for success of the kind expressible in cash. The consciousness of service must suffice as the sole reward. Discoveries creep gradually into public consciousness; suddenly they may become the latest marvel of science, only to develop in a very brief period into a commonplace of existence.

The rate of progress made by science in providing the amenities of life during so short a period as the last decade is amazing, but there is still something to be done to accelerate the coming of a future such as pictured by H. G. Wells, in which we have a control over many things which to-day seem to us almost sacred. The public readily appreciates a showy building; it must be brought to realise that it is experimental research which at all times needs endowment. Most of all, however, we must beware that the budding genius is left unfettered and not destroyed at the beginning of his career, by the system of examinations at school and college. Such mediocrity is exhibited by the papers published in our scientific transactions and proceedings that one can but have serious anxiety in this respect. It is made far too difficult for the unorthodox and eccentric young man to gain his chance of promotion: the investigator in fields of inquiry which are not the fashion of the moment often finds it hard to gain recognition and support.

The ultimate aim of all scientific research is to better the position of man; chemistry in particular, now that the knowledge of the structure and behaviour of the individual substances has been mastered, is in a position to help in the greater biological field. There must be a chemical basis to growth, to senescence, to heredity, even to personality, and all else that happens in the body. Robertson began in Australia the study of such questions as the value of phosphates on wool production, and of a cystine-high diet on the quality and quantity of this staple production of the country, experimenting with so many as 80,000 sheep. He makes a plea in one of his essays for the fostering of research on a large scale in the wide open spaces of the earth, instead of concentrating it in laboratories among the crowded centres of population.

It is an axiom that a well-balanced mind is essential for a research worker of the highest class, however much he may be a specialist in his laboratory. To be appreciative of art, of literature and of music, with a love for his country, his home and his work are desirable attributes. Such a man was Brailsford Robertson, and the keen spirit of enjoyment which permeates his essays makes them worthy of more than passing perusal.

E. F. A.

Hydrodynamics

Bulletin of the National Research Council, No. 84: Report of the Committee on Hydrodynamics, Division of Physical Sciences, National Research Council. Pp. ii + 634. (Washington, D.C.: National Academy of Sciences, 1931.) 4·50 dollars.

IN each of the processes involved in the study of fluid motion—in observation, measurement, physical explanation, and calculation—this century has seen notable advances. There are improved methods of making the flow visible, and a technique for measurement in thin layers of fluid next to solid boundaries. Enlightenment and understanding have followed recognition of the importance of the motion in such layers, which to some extent has proved amenable to calculation. Such calculations are important mathematical advances; but to most mathematicians the greatest achievements are probably those resulting from skilful use of ideal fluid theory, with circulation and vorticity included. There has been progress in turbulence theory, and in research on compressible fluid flow; and though, on the whole, most attention has been paid to motion past obstacles and in pipes, with their technical applications, it must be remembered that the study of waves and tides has not been without incident in recent years.

There is, then, a wide field on which to report. In any one-volume report selection will be necessary, and we turn to the volume before us to determine first how the selection has been made. Without preface or foreword, after a scanty contents table, the book opens with a short chapter by Dr. H. L. Dryden, which, called a general survey of experimental hydrodynamics, actually summarises experiments on flow past obstacles. Aerofoils occupy a small space; airscrews are not mentioned. In the next chapter Prof. F. D. Murnaghan gives an elementary presentation of monoplane aerofoil theory, and the parts of ideal fluid theory necessary for it, together with an inadequate account of calculations of flow past a body of revolution.

The rest of the book is by Prof. H. Bateman. In the third chapter, which closes the first part of the report, he writes on the general physical properties of a viscous fluid. There are three more parts—on the laminar motion of a viscous fluid, on turbulent motion, and on compressible fluids—each fairly full. The number of references given is enormous. Each of the first two chapters, and each small section of Prof. Bateman's, is followed by a bibliography, and there are additional references at the end of the book. Many matters not dealt with in the text are mentioned in these bibliographies, which seem, indeed, extraordinarily comprehensive.

The committee has thus succeeded in giving full reports on viscosity, turbulence, and compressible fluids by sacrificing large portions of ideal fluid theory. The omission of waves and tides reflects the influence of aeronautics on hydrodynamical research; and while reports on Levi-Civita's extension of the mathematics of free stream-line motion, the use of integral equations, and approximate numerical solutions would have been welcome, most striking is the omission of a discussion of the Kármán vortex street and the resulting drag formula, all the more so since the presentation of aerofoil theory is similar, in some places, to Glauert's, and space could have been saved by a reference to his book. It is a pity, too, that room could not be found for descriptions of experimental technique.

Dr. Dryden's chapter is one of the best, but too short. Experimental results are summarised as well as possible in the space, and modern theories receive due mention. There are, however, no pictures, diagrams or tables. To print a chapter on experimental hydrodynamics without any of these aids to the understanding is an unwelcome innovation for which no price reduction can make amends.

Prof. Murnaghan's account is connected; his mathematics is clear, and well decorated with illustrations; but the account is restricted to rather elementary matters, and airscrew theory is completely omitted. The insistence on the *ad hoc* nature of hypotheses in Prandtl's aerofoil theory is unfortunate; the theory is a first order theory capable of development in a rational manner. Prof. Murnaghan's one innovation in the theory is to suggest that the downwash should be compounded with the velocity at the trailing edge, rather than with the undisturbed velocity, in the usual calculation of induced drag. But the velocity at the trailing edge is zero if the angle there is finite. The confusion probably results from a lack of understanding of the approximations.

Prof. Bateman presents us with an embarrassing wealth of information, drawn from many sources, at times presented somewhat uncritically, and not easy to read. The report often has the character of a number of results loosely strung together. The treatment of laminar viscous flow is largely mathematical; formulæ abound; tables and diagrams are absent; so that, of quantitative results, only those expressible by formulæ are presented. Thus the drag on a plate according to boundary layer theory is given, but not the velocity distribution. Neither here nor in the first chapter is there comparison with experiment. How we miss those diagrams!

The reporting appears to be generally accurate, but when so wide a field is covered, errors are inevitable, and some five or six have been noted. Too much space seems to have been given to mathematics with minute physical significance. Occasionally important results remain buried in the bibliographies; and sometimes, also, certain matters find their only mention in odd company. There is an unwillingness to include any detail about general physical ideas; several examples might be given, of which one of the most important is the complete lack, anywhere in the book, of an adequate discussion of the production of circulation and vorticity in fluids of small viscosity.

It is not easy to find the place. The index is far from complete, and the page headings do not help—always "Hydrodynamics" on the left and the title of the part on the right. Prof. Bateman's frequent omission to give references to papers previously mentioned wastes time. But these are minor blemishes on a valuable work of reference to the making of which has gone great learning and knowledge. There is, indeed, a vast store of information here, much of it not to be found in any other book in English. S. G.

Oceanographical Work of the *Carnegie*

The Last Cruise of the Carnegie. By J. Harland Paul. Pp. xvii + 331. (Baltimore: The Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1932.) 26*s*. 6*d*. net.

THREE years ago the *Carnegie* met her fate when at anchor in Samoa owing to an explosion when loading gasoline for her auxiliary engine. The loss of a fine vessel, built expressly for the study of terrestrial magnetism, was a catastrophe, but this was completely overshadowed by the death of Capt. Ault, fine seaman, skipper and navigator, enthusiastic and generous scientific chief. The *Carnegie* was the most widely known of all vessels, for she had already made six cruises mostly across unknown areas of sea and visited many strange ports. Capt. Ault was in command of three of these, and this story of her seventh cruise is eloquent as to his practical qualities and to his high efficiency as leader. Ventures and dangers are passed by so lightly, as in recent War dispatches, that at times the reader wonders whether the author appreciated them and understood fully the quality of his 'skipper'.

The *Carnegie* was a brig, 128 ft. on the loadline, 155 ft. over all and 33 ft. beam, drawing 14 ft. and setting about 13,000 sq. ft. of canvas, with auxiliary engine of small power. She was built on fine yacht lines and usually set a large leg-of-mutton mainsail. Her peculiarity lay in her build, no iron being used in any part and even avoided in loose tools and gear. This, while highly advantageous to her studies of terrestrial magnetism, had obvious disadvantages, manila rope not forming a good anchor warp, as off Easter Island where it was cut through on the rocks. Phosphor-bronze was a poor substitute for steel in the wire on the winches. This was necessary, for the seventh differed from the earlier cruises in that oceanographic stations were to be established, depths, temperatures, salinities and other chemical factors to be observed, while plankton was to be collected from various depths. Echo sounding gear was also fitted, to be checked by bottom sounding. Clearly no expense was spared in attempting to obtain perfection in equipment, but nevertheless unforeseen accidents were numerous, the sonic gear being out of commission at one period. At the same time, great attention was to be paid to atmospheric electricity and to air movements aloft, so far as could be observed by balloons, to prepare the future "Sailing Directions" for aeroplanes. Further, perhaps an embarrassing feature, the ship was seldom out of touch by radio with her headquarters at Washington, although sailing in the most distant waters of the Atlantic and Pacific Oceans.

The cruise started on May 1, 1928, and Plymouth and Hamburg were visited for intercomparison of instruments and methods and for additional gear. The course was then set to Iceland, often a bad landfall on account of local compass deviations which demand constantly checked variation charts. Dr. Paul is enthusiastic of this land of "the mother of parliaments" with its culture, "the highest general level of our whole cruise". Regular oceanographic stations were taken across the Sargasso Sea and thence westwards to Barbadoes and Panama, where the *Carnegie* went into dry dock. It was a hard fight to clear the Galapagos and so out into the Pacific, the run to Easter Island taking 42 days. Then follows an excellently illustrated description of this ever-interesting land, famous for its carved figures, centre of a weird civilisation, an everlasting and probably insoluble problem. The suggestion put forward here is that of a relic island of a once large archipelago, but we have failed to find any scientific evidence for any great lands in the mighty Pacific's waste of water.

To reach Callao a great loop to the south-east had to be made to catch the 'westerlies', the least known of ocean areas being traversed. Sectional charts of water temperatures and salinities give food for thought, and an offshore ridge was charted rising 10,000 ft. to within 650 fathoms of the surface. The *Carnegie* then picked up the 'trades' to Tahiti and Samoa, keeping well to her line of latitude and carrying out her routine of magnetic, electrical and oceanographical observations highly successfully. The Tuamotu Group was crossed, but we searched in vain for any hint as to the shape of the underlying foundations of this great coral group. Good samples of the bottom deposits were secured and should prove interesting. A sailing vessel, however, was clearly not suitable for much of the oceanographic work, for to secure the best samples it is advisable to keep the ship's head to sea with the engines going slowly so that she makes no way. The warps for bottom samplers and for water and plankton nets ran out at sharp angles, as much as 75° from the vertical, and closing or reversing messengers were often hung up by animals unintentionally caught up on the wires. The latter sometimes fouled, for apparently the staff tried to carry on all their observations synchronously, and the loss of water bottles and thermometers was so considerable that the captain must have heaved a sigh of relief when he again got his ship on her course.

From Samoa to Guam, a prosperous United States colony, was clear sailing, and *en route* to Japan was obtained the deepest sounding of the cruise, 8,350 metres. Tokyo was reached after typhoon experiences which must have tried the *Carnegie*. The voyage thence to San Francisco, 36 days, on a very northerly course, heavy seas, overcast skies and perpetual foghorn cannot have been a happy experience, but there were doubtless consolations in a well-earned rest in the home port.

The further plan of the cruise included a visit to Australia and a complete circumnavigation of the world before the 'westerlies' of the Southern Ocean. Hawaii came first and then the tragic end in Apia Harbour, famous in our naval annals for the feat of the *Calliope* in putting to sea in a hurricane, when six war vessels piled up on that harbour's shores.

The scientific results of the *Carnegie* had all been dispatched home before her end, and Dr. Paul's narrative is a desirable supplement telling us how they were obtained. It is a pleasing and instructive story for all who "go down to the sea in ships"—but why is the vessel pictured on the binding as an idealised three-master that never could have sailed on any sea ? J. S. G.

Short Reviews

The Law of Patents for Chemists. By Dr. J. Rossman. Pp. ix+304. (Washington, D.C.: The Inventors Publishing Co., 1932.) 3.50 dollars.

DR. ROSSMAN has packed into this volume much information that is of interest to chemists in Great Britain as well as in the United States, and the sections on essential patent law principles and on the procedure for obtaining the patent are of general interest although primarily relating to American patent law. From this point of view the book should be of real value to chemists in providing a comprehensive survey of the technicalities of patent law in a manner which is intelligible to chemists without legal training. A glossary and a bibliography of books and periodicals add to its general utility.

From a broader point of view the book is disappointing. At a time when the evil of paper patents is generally acknowledged and is so serious and widespread that the suitability of the patent system to modern industry, and especially chemical industry, has been openly questioned, it is surprising to find that the chapter on "What is Invention ?" indicates little appreciation of the fundamental problems which now arise in the relations between scientific and industrial research and invention. These difficulties have been ably delineated by Mr. C. C. Paterson in an appendix to the Report of the British Science Guild on the "Reform of the British Patent System". Similar difficulties exist in the United States and some indication of the attitude of patent law opinion in that country, particularly on the suitability under modern conditions of 'inventive ingenuity' as subject matter for a chemical patent would have been welcome, as well as reference to the related question of protecting scientific discoveries or scientific property. These should not have been omitted in a book addressed to scientific workers, and the brief discussion on patent rights, particularly those of employer and employee, would have gained value from a broader vision and from reference to the studies on the position of the salaried inventor carried out for the International Labour Office and the League of Nations in recent years.

Forensic Chemistry and Scientific Criminal Investigation. By A. Lucas. Second edition. Pp. 324. (London: Edward Arnold and Co., 1931.) 18*s*. net.

THE second edition of this excellent textbook appears at a time when a reminder of the immense services which the man of science can render in the prevention and detection of crime is more than opportune. Recent discussions on the increase of crime in Great Britain during the last two or three decades have suggested doubts as to whether the authorities are making sufficiently full use of the resources of science in protecting society against those who are prepared to prostitute the discoveries of science for criminal purposes. The new and enlarged edition of this book includes references to many of the important advances which have been made during the ten years since the first edition was published, in the use of scientific methods for the detection of the criminal, notably the use of ultra-violet light.

Much of the book has been rewritten, related chapters having been combined and a considerable amount of new matter has been incorporated, particularly in the chapters on bloodstains, clothing, documents, explosives and explosions. The expansion of the chapter on firearms, cartridges and projectiles well illustrates the growing importance of this subject due to the greatly increased use of firearms for criminal purposes since the War. Excellent bibliographies accompanying each chapter and numerous references in the text enhance the value of a well-written and up-to-date book, which may be read with interest even by those who are not experts in forensic chemistry.

To the general reader it will enforce the conclusion drawn by the author in his introduction—"the criminal is becoming so scientific not only in his work but in the means he adopts to escape detection, that a scientist is needed to cope with him". The scientific reader will mark that from yet a further point of view his services are urgently demanded by society.

A Text-Book of Organic Chemistry. By Prof. Dr. Julius Schmidt. English edition by Dr. H. Gordon Rule. Second edition, revised and extended. Pp. xxiv + 843. (London and Edinburgh: Gurney and Jackson, 1932.) 25*s*. net.

WE learn from the preface that the two-fold purpose of the author in revising the text of the first edition was to incorporate the main advances which have been made in the subject and to avoid any appreciable increase in the size of the book. An analysis of the distribution of the 45 pages that measure the increase in the size of the book affords a very fair estimate of the conspicuous success with which the author has achieved his object; for 29 pages go to the general section, 8 to the text dealing with the systematic treatment and 8 to the index.

The large extension in the general section enhances considerably the value of the book, for it includes discussions on such subjects as addition to conjugated systems, the electronic theory of valency, the mechanism of racemisation, epimerisation, conditions for enantiomorphism, isomerism due to restricted rotation around a single bond, asymmetrical decomposition, spiro-compounds, the stereochemistry of nitrogen and sulphur, the Beckmann re-arrangement, tautomerism, the parachor, polar properties of organic compounds and factors influencing the magnitude of optical rotatory power. All these subjects are treated with admirable clearness and supplied with full bibliographical references, and certain of them—the one dealing with tautomerism in particular—are valuable monographs on the subjects.

In the text dealing with the systematic treatment, the whole subject has been carefully revised and brought up to date, and the increase of only 8 pages in this section affords no measure of the extent or completeness of this work. For such a measure we turn to the index, in which an increase of 8 pages represents some 360 and 600 new names of authors and subjects respectively.

Die Tierwelt der Nord- und Ostsee. Begründet von G. Grimpe und E. Wagler. Herausgegeben von G. Grimpe. Lief. 21. Teil 1.d$_2$: *Einführung in die Hydrographie der Nord- und Ostsee*, von Bruno Schulz; Teil 2.g: *Sporozoa*, von Eduard Reichenow. Pp. 45 - 88 + 88. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1932.) 12 gold marks.

THE latest portion of this useful work begins with a concise and good general account of the hydrography of the North Sea and Baltic, with charts and diagrams, occupying forty-four pages. The remaining eighty-eight pages are taken up by a treatise on the Sporozoa. Omitting the Sarcosporidia as only occurring in the muscles of land vertebrates, Dr. Reichenow divides the group into Telosporidia, Cnidosporidia and Haplosporidia. Most of the known forms belong to the Telosporidia, a fair number to the Cnidosporidia and only a very few to the Haplosporidia. Marine Sporozoa are found in various worms, especially polychætes, in echinoderms, molluscs, crustaceans and tunicates, besides several in fishes. The author wisely places in his lists many species which have not yet been found in the area dealt with, but as they occur in the Mediterranean, parts of the English Channel and the west of Scotland, the distribution may easily extend farther and their inclusion adds much to the value of the work. This also applies to the general account of the structure and biology which covers all these species and not only those so far found in the North Sea and Baltic. Good descriptions and figures are given and the life-histories of many forms are illustrated.

The whole group is extraordinarily interesting and one in which there is still a large amount to be still discovered. Among the Haplosporidia is the unusual case of a sporozoon (*Anurosporidium pelseneeri*) contained in trematode sporocysts of two genera which themselves parasitise the mollusc *Donax trunculus*.

A Manual of Clinical Laboratory Methods. By Dr. C. L. Cummer. Third edition, thoroughly revised. Pp. xx-17-585. (London: Henry Kimpton, 1931.) 30*s*. net.

THE third edition of Prof. Cummer's manual maintains the high standard of the former, and the same policy of conciseness is apparent in the new material which has been introduced. Perhaps the most important additions are the more detailed description of Kahn's reaction for the diagnosis of syphilitic infection, and a full technique for the carrying out of Kline's reaction for the diagnosis and exclusion of syphilis. Among other recently developed tests in biochemistry mentioned are the erythrocyte sedimentation rate, Ehrmann's alcohol test meal, the use of histamine as a gastric juice stimulant, and agglutination tests for tularemia and undulant fever. The Queckenstedt test for sub-aracknoid block is described, but its interpretation is very loosely worded. The author also includes now the long-established Alzheimer method for identifying different types of cells in the cerebrospinal fluid, and the silver staining for treponemata.

This book can confidently be recommended to biochemists and laboratory workers as containing almost everything required for routine work. For the next edition the author might consider including details of blood calcium estimation, and possibly methods of estimating phosphate and lecithin in the blood. For blood cholesterol, also, an all-glass method of percolating the thimble is preferable to that still included.

Origin of Tektites

By Dr. L. J. SPENCER, F.R.S.

SMALL, curiously shaped pieces of green, brown, or, more usually, black glass have long been known from certain regions, and have been called moldavites from the Moldau River in Bohemia and from Moravia; australites or obsidianites from Australia; billitonites from the tin-bearing gravels in the island of Billiton, Dutch East Indies; and Darwin glass from Tasmania. They have also recently been found in some abundance in French Indo-China and in the Philippine Islands. In chemical composition they are peculiar in containing a very high percentage of silica (SiO_2, 70–89 per cent).

Many theories have been advanced to account for the origin of these bodies, which are known collectively as tektites. Those from Bohemia and Moravia were formerly thought to be relics from a prehistoric glass factory. They have been thought to be 'bombs' or bubbles shot out from volcanoes (even from volcanoes on the moon). The fusion of atmospheric dust or desert sand by lightning has been suggested. Another theory is that they are colloidal bodies formed by the action of humic acids on the underlying rock in certain climates. The view most generally accepted at the present time is that they are meteoric, although they are entirely different in all their characters from any meteorite that has been actually observed to fall.

In a recent elaborate and beautifully illustrated monograph[1] Prof. A. Lacroix gives a detailed review of the whole question. He elaborates a suggestion first made by H. Michel in 1925 that tektites have been formed in the earth's atmosphere from meteoric material consisting of the element silicon and the lighter metals (aluminium, calcium, potassium and sodium). Such material heated by friction with the air would rapidly oxidise with the production of a temperature sufficient to fuse the products of oxidation; and subsequent rapid cooling would yield a glass.

Although much has been written on the subject of tektites, the elementary fact that the material of which they are composed is really an impure silica-glass has been entirely overlooked. Pure silica-glass has a specific gravity of 2·20 and refractive index 1·46—both low values. The values for tektites are 2·27–2·51 for the specific gravity and 1·48–1·52 for the refractive index.

Now the 'cinders' of the legendary city of Wabar, 'destroyed by fire from heaven', which was discovered early this year by Mr. H. St. J. Philby in the Rub' al Khali, Arabia,[2] consist of such a silica-glass. The vesicular white glass contains SiO_2, 92·88 per cent, with specific gravity 2·10 and refractive index 1·468; whilst the black glass, almost free from bubbles, contains SiO_2, 87·45 per cent, with specific gravity 2·24 and refractive index 1·50. The black glass contains also Fe_2O_3, 0·28; FeO, 5·77; NiO, 0·35 per cent. At this spot pieces of meteoric iron were found, the largest rusted remnant weighing 25 lb.; and also a series of craters that must have been formed by the impact of a shower of large meteorites. When a large mass of iron travelling with planetary velocity is suddenly stopped, the kinetic energy ($\frac{1}{2}mv^2$) is transformed into heat at a localised spot with the development of a very high temperature. The 'bombs' of silica-glass collected by Mr. Philby at Wabar suggest there must have been a pool of molten silica in the desert sand and that this material was shot out from the craters through an atmosphere of silica, iron, and nickel vapours.

At the group of meteorite craters discovered in 1931 near Henbury in Central Australia[3] silica-glass has also been found, but in smaller quantity and only around the largest crater. Here the country-rock is a ferruginous sandstone and the glass that resulted from the fusion of this rock is black and less pure. It contains SiO_2, 68·88 per cent and has specific gravity 2·31 and refractive index 1·545. It also contains Fe_2O_3, 8·46; FeO, 7·92; NiO, 0·28 per cent. Nickel is not shown in analyses of tektites, probably because it was not suspected and not looked for.

The pieces ('bombs') of silica-glass from both Wabar and Henbury present many similarities to tektites; especially to the Darwin glass from Tasmania, with which some can be matched exactly in both form and appearance. Beads and tear-shaped drops are common and there are some disc-shaped pieces, but none with the perfect button-like shape of true australites. I have been much struck with this similarity, but now that I have seen pictures of the tektites from Indo-China given by Prof. Lacroix in his monograph, I have no hesitation in concluding that tektites are not meteoric, though they are connected with the fall of large meteoric masses, but that they have resulted from the fusion of terrestrial rocks, especially in sandy deserts, by the heat so developed.

Silica-glass and tektites could, of course, be formed only in very exceptional circumstances. The fall of very large meteorites on the earth's surface is fortunately not of frequent occurrence. With the possible exception of the still debatable Siberian fall on June 30, 1908, none has in fact taken place during historic times. Further, the terrestrial rock at the place of fall must be of the right kind, such as sandstone or quartzite, or perhaps best of all a clean desert sand. The composition of tektites indicates that a certain amount of felspar, mica, or clayey material was present in the rock (arkose or siltstone); and no doubt these extra constituents (Al_2O_3, 12; CaO, 3; K_2O, 2; Na_2O, 1 per cent) gave to the molten material just the right viscosity for it to assume particular shapes when spinning through the air after being shot out by the gaseous explosion from the meteorite crater. The craters, supposed to be meteoric, on the Island of Oesel in Estonia are in dolomite, while the rocks in the region of the Siberian fall are basaltic. In neither of these places could silica-glass and tektites be formed.

Silica-glass is very resistant to chemical action and it will withstand weathering processes longer than many other materials. Also, with its very low coefficient of thermal expansion, it will not be affected by changes in temperature—a very potent agent of rock disintegration in desert regions. For this reason tektites are preserved in recent deposits, such as the glacial deposits of Tasmania, the alluvial deposits of Bohemia, Indo-China, and the Philippine Islands, and in the tin-gravels of Billiton, where by slow chemical corrosion they have acquired a peculiar sculptured surface. The australites found on the surface of the Australian deserts do not show this surface sculpturing and are more perfect in form. They are therefore of more recent origin. An aerial survey of the districts where australites are found would probably reveal the presence of meteorite craters with associated large masses of meteoric iron. In the other districts, all traces of the craters would probably have been obliterated by denudation, and the meteoric iron rusted away.

Recent Research on the Vitamins

ADVANCES in our knowledge of the chemistry of the vitamins have recently been so rapid that a review of the position at any moment may require correction or amplification almost as soon as it is published. A useful summary of our knowledge of the nature and function of vitamins was provided in April and May of 1932 by Prof. J. C. Drummond in his Cantor lectures.[1] Some of the points made by the author may be briefly referred to here, and opportunity taken at the same time to review work which has been published since the delivery of the lectures.

Prof. Drummond summarises some of our knowledge in tabular form: the charts showing the minimum effective doses of the different vitamins in test animals, the functions and properties of the six B vitamins, and the distribution of the vitamins in foods are specially useful. He considers first the water-soluble vitamins C and B. The work of O. and A. Rygh and P. Laland[2] on the antiscorbutic potency of narcotine derivatives has not been confirmed by S. Smith and S. S. Zilva[3]. Daily doses of 1·37, 2·75 and 5·5 mgm. of dimethyl and methyl*nor*narcotine had no protective effect in guinea pigs kept on a scorbutic diet. It is possible that the doses were incorrectly chosen as Rygh *et al.* state that only optimal doses prevent the onset of scurvy in guinea pigs on a scorbutic diet. On the other hand, the fact that all Rygh's animals given narcotine derivatives died like the controls indicates that these supplements are not acting in the same way as a daily dose of lemon juice.

Negative results have been described also by other observers, including L. J. Harris and I. Mills, who found that irradiated narcotine and methyl*nor*narcotine were not antiscorbutic in doses ranging from 10 mgm. to 0·001 mgm. daily.[4] Zilva[5] and his colleagues have recently published full details of their work. No narcotine could be isolated from unripe orange juice by ethereal extraction, nor was a concentrate of vitamin C obtained from lemon juice by such means. Methyl*nor*narcotine in daily doses ranging from 10 γ to 2·7 mgm. had no antiscorbutic effect at all in guinea pigs maintained on a scorbutic diet, the experimental animals dying in 30–35 days with all the signs of severe scurvy.

Reference has already been made in these columns to the claim that vitamin C is a hexuronic acid[6]. The experiments on which the claim is based have now been published in detail.[7] Svirbely and Szent-Györgyi found that 1 mgm. of their product daily completely protected guinea pigs on a scorbutic diet from scurvy for 90 days: the animals also showed normal growth during this period. The minimum protective dose of lemon juice is usually regarded as 1·5 c.c. and this quantity contains approximately 0·5 mgm. of the acid. Since the substance contains a molecule of water less than is required for a hexuronic acid, Szent-Györgyi and W. N. Haworth have now suggested the name "ascorbic acid" for it (NATURE, 131, 24; 1933). Waugh and King have also isolated a crystalline solid from lemon juice which was protective in a daily dose of 0·5 mgm. The possible objection that the material isolated from lemon juice was merely contaminated with a more potent antiscorbutic substance is not valid in the case of the work of the former authors, since the acid used was prepared from ox suprarenal glands. If the antiscorbutic factor is ascorbic acid, it is necessary to explain Zilva's observation that it is possible to oxidise the reducing factor in lemon juice without destroying the antiscorbutic potency, although the vitamin is now very labile: Svirbely and Szent-Györgyi suggest that in these conditions the acid may be present in a reversibly oxidised state. The antiscorbutic potency of this acid has been confirmed by Harris and Mills (*loc. cit.*), who also found raw suprarenal cortex potent, the activity running parallel to the acid content.

Turning to vitamin B, Prof. Drummond reviews the work of Jansen and Donath, Odake, and Windaus and his co-workers on the chemistry of vitamin B_1.[8] All observers now agree that the crystalline vitamin contains sulphur in its molecule, as well as carbon, hydrogen, oxygen and nitrogen.

H. W. Kinnersley, J. R. O'Brien and R. A. Peters, in a recent communication,[9] also confirm this observation: their crystals were obtained from bakers' yeast, and the hydrochloride is active in a pigeon day dose of 2–4 γ (a pigeon day dose is approximately equal to 1·5 vitamin B_1 international units). Windaus's preparation is active on pigeons in doses of 1·4–3·3 γ: both are more active than Jansen and Donath's original preparation, which contained also vitamin B_4.

Vitamin B_1 is usually considered to be a base. Examination of a number of bases for antineuritic or growth promoting powers has, however, so far given negative results. B. C. Guha and P. N. Chakravorty have recently announced in these columns[10] that irradiation of adenine sulphate with ultra-violet light confers vitamin B_1 properties upon it. In this connexion work on the absorption spectrum of vitamin B_1 concentrates has some interest: a band at 2600 A. was found by Guha[11], Windaus (*loc. cit.*) and others. F. F. Heyroth and J. R. Loofbourow have recently reviewed the question and reported some experiments of their own.[12] The absorption spectrum of yeast nucleic acid shows a band of maximum absorption near 2600 A., suggesting that vitamin B_1 concentrates contain purine or pyrimidine compounds. Irradiation of uracil or thymus nucleic acid increased the absorption between 2300 and 2550 A. No decrease in the absorption at 2600 A. was observed when only wave-lengths longer than 2960 A. were used for the irradiation. After irradiation, uracil and adenine develop a blue colour with arsenophosphotungstic acid, similar to that given by vitamin B_1 concentrates. Heyroth and Loofbourow found a fairly close correlation between potency and absorption at 2600 A. in the purest concentrates examined. Compounds which are likely to absorb in this region are those containing a pyrimidine-ring or those closely related to ergothioneine (betaine of thiolhistidine). This suggestion is of interest in view of the fact that vitamin B_1 is now held to be a sulphur compound.

It appears likely that pure crystalline vitamin B_1, prepared synthetically, will be available in the near future, as pure crystalline vitamin D is available to-day. Meanwhile, the animal test must be the final criterion. To ensure comparable results in different laboratories, the Permanent Commission on Biological Standardisation of the League of Nations has recommended the issue and use of a fuller's earth adsorbate from rice polishings as a standard for vitamin B_1, 10 mgm. of which is defined as containing one unit. H. Chick and H. M. Jackson[13] report on the use of this preparation. It has been found stable for a year, its vitamin B_2 content is only 1/25–1/50 of the vitamin B_1 present and it also contains vitamin B_4.

Prof. Drummond referred briefly to the recent work on the physiology of vitamin B_1 and emphasised the importance of distinguishing between the changes due to inanition and those caused by a deficient intake of vitamin B_1 *per se.* N. Gavrilescu and R. A. Peters[14] have found that the oxygen uptake of parts of the brain in pigeons suffering from polyneuritis is definitely below normal. Administration of vitamin B_1 to the birds or its addition to the minced brain tissue *in vitro* resulted in an increase in its consumption.

Prof. Drummond also summarised our knowledge concerning vitamin B_2. He considers that it is a neutral and not a basic substance, with a molecular weight greater than that of vitamin B_1.

Some recent work on vitamin B_4 may also be mentioned here. Absence of this vitamin from the rat's diet produces redness and swelling of the paws, a spastic gait and loss of co-ordination. Convulsions and paralysis are the characteristic signs of vitamin B_1 deficiency.[15] H. Barnes, J. R. O'Brien and V. B. Reader[16] describe the preparation of a crystalline compound with vitamin B_4 activity, having the empirical formula $C_4N_4H_6Cl$. It was obtained from yeast extract by adsorption on charcoal at *p*H 1. The charcoal was extracted with 50 per cent acid alcohol, the alcohol removed *in vacuo* and the extract subjected to successive treatments with mercuric sulphate, baryta, sulphuretted hydrogen and sodium phosphotungstate. A crystalline phosphotungstate was precipitated at *p*H 2 and recrystallised from 50 per cent alcohol. It was then dissolved in 50 per cent acetone, and the phosphotungstic acid removed with baryta; the acetone was removed from the filtrate, which was hydrolysed with 5 per cent hydrochloric acid: the solution was concentrated and alcohol and ether added. Crystals were deposited, with melting point 248° (with charring).

Although highly potent preparations of vitamin A have recently been obtained, it has not been found possible to crystallise them. Prof. Drummond refers to the recent work of Karrer, Morf and Schopp, suggesting that vitamin A is an unsaturated alcohol, having the empirical formula $C_{20}H_{30}O$ or $C_{22}H_{32}O$, its structure being related to half the carotene molecule.[17] I. M. Heilbron, R. A. Morton and E. T. Webster[18] have confirmed this suggestion. A concentrate was heated with finely powdered selenium at 300°–330° for 48 hours, and the product extracted with ether. After removal of the solvent, the oil was distilled over metallic sodium; the fraction distilling at 120°–200°/20 mm. was treated with picric acid, when the orange crystals of 1 : 6–dimethyl naphthalene picrate were obtained.

I. M. Heilbron, R. N. Heslop, R. A. Morton, E. T. Webster, J. L. Rea and J. C. Drummond[19] have described the properties of the most concentrated preparations of vitamin A, which they have recently obtained from halibut liver oil. The unsaponifiable fraction was obtained, freed from sterols and fractionally distilled at a pressure below 0·00001 mm. The main fraction distils at 137°–138°, with increase in potency. It is a pale yellow viscous oil which becomes mobile on warming, and is readily soluble in organic solvents; at 3280 A. $E^{1\text{ per cent}}_{1\text{ cm.}} = 1,350$ and the Carr-Price blue value is about 65,000. The analytical figures agree fairly well with those required for the formula $C_{20}H_{30}O$. Similar concentrates were prepared from sturgeon liver oil and mammalian liver fat, but the best material obtained from cod liver oil was only about half as pure. Biological tests on rats showed that daily doses of 0·025–0·1 γ cured xerophthalmia and promoted growth.

The antimony trichloride test indicates that these concentrates still contain variable quantities of a substance which is chromogenic but is different from vitamin A itself. The blue colours obtained with sturgeon and halibut liver oil concentrates show an absorption band at 6930 A. the intensity of which is usually a quarter of that of the band at 6170 A. but in halibut concentrates may be only one-tenth ; moreover, no selective absorption was observed at 6930 A. in mammalian concentrates. Morton[10] has found that the addition of 7-methylindole to the concentrate inhibits the development of the band at 6170 A. before that at 5830 A. is appreciably affected. In the richest concentrates the intensity of the band at 6170 A. is almost twice that of the band at 5830 A. If 7-methylindole is added to the concentrate in the ratio 4 : 1 (or 10 mol. to 1 mol.) the two bands appear of roughly equal intensity. The band at 6930 A. is not readily inhibited by this reagent. The independence of the two bands at 6170 A. and 5830 A. indicates either that two chromogens are present or that vitamin A reacts with antimony trichloride in two stages.

Reference has already been made in our columns to the possible correlation between the biological test and certain of the chemical and physical characteristics of oils containing vitamin A.[11] Another series of cod liver oils has now been examined and further tests have been performed on some of the previous series.[12] The variations between the different methods were greater than in the earlier series of tests, but it still appears that the intensity of the band at 3280 A. in the oil itself forms the best measure of its biological activity. The antimony trichloride test was not so satisfactory, although in the case of certain oils, when it was carried out on the unsaponifiable fraction of the oil, a correlation was found between the blue value and the biological activity. The biological tests had a large margin of error. It was found advisable to compare a sample with the standard oil in simultaneous tests rather than to rely exclusively on the curve relating growth to dose given obtained with the standard oil at some earlier date.

R. J. Norris[13] has also noted marked discrepancies between the biological and colorimetric methods of assay. The course of the inactivation of vitamin A by irradiation with ultra-violet rays was also followed. An initial latent period was found by biological test but not colorimetrically ; after four hours' irradiation, all the vitamin had been destroyed, but the colour test indicated that the potency had only been reduced about 25 per cent. The destruction of the chromogen follows the course of a bimolecular reaction.

The discrepancies may be explained in part by the error of the biological test and by the presence in oils containing vitamin A of substances which interfere with the development of the blue colour in the Carr-Price test or with its determination. R. S. Morgan[14] has found that the presence of any red in the colour estimated reduces the value of the blue.

The details of the conversion of carotene to vitamin A in the animal body are as yet unknown. The absorption of carotene from the intestine is a slow and incomplete process ; it is apparently related to the fat content of the diet. Small amounts may be found in the liver, but it appears that the bulk of the absorbed material is stored in that organ in the form of vitamin A.[15] The conversion presumably occurs in the liver, but Ahmad was unable to confirm the observation of Olcott and McCann that this organ contains an enzyme which converts carotene into vitamin A *in vitro*. When the diet is rich in carotene, the vitamin A stores in the liver are high. The stores are utilised when the diet is deficient in carotene or the vitamin, but the exact function of the latter in metabolism is unknown. W. J. Dann has shown that it is only with difficulty passed into the mother's milk, so that to build up a store in young animals it is necessary to give it directly to the latter[16] ; also in the rat, at least, very little reaches the young via the placenta. The failure of growth on a vitamin A deficient diet is not entirely due to loss of appetite. Rats on this diet may consume as much food as their litter mate controls given a supplement of vitamin A, but the amount of nitrogen deposited in the body is less and the amount excreted in the urine greater than in the latter, indicating an increase in the nitrogen metabolism. The increase of body-weight per gm. of food eaten is less when the animal has not available an adequate amount of vitamin A.[17] Vitamin A is apparently necessary for the deposition of body tissue. It is well known that certain epithelial surfaces cannot maintain their proper structure when the animal's stores are depleted, with the result that infectious processes develop in different regions of the body. Thus both the growth-promoting and the anti-infective properties of vitamin A appear to depend fundamentally upon its ability to maintain a normal structure in the different tissues of the organism.

The story of the isolation of crystalline vitamin D is now well known and has been referred to previously in these columns.[18] Prof. Drummond reviews the different investigations leading to its isolation in his third Cantor lecture and also refers in considerable detail to Mrs. Mellanby's work on dental caries, which has also been described in NATURE[19]. With the preparation of the pure vitamin, biological tests have become of less importance ; the earlier production of highly active compounds and their use in clinical practice led, however, to a great increase in the number of such tests required, with the result that methods were standardised and their accuracy increased. We have already referred to the analysis of the curative radiographic method given by Bourdillon and his colleagues.[30] Working with Miss Bruce, he has recently completed a comparison of the prophylactic radiographic method with that based on bone analysis.[31] A radiographic scale was prepared showing eight stages from full rickets to normal bone. The relation between scale reading and logarithm of the dose was not linear. With bone analysis, on the other hand, the relation between percentage of bone ash and logarithm of dose was linear between doses of 0·03 and 0·32 unit vitamin D. An analysis of the errors of the different methods leads the authors to the following conclusions: the accuracy attainable is greater with bone analysis than with the use of a radiographic scale, using the prophylactic method, and the range of doses possible is greater; but the method of bone analysis has about the same degree of accuracy as the radiographic when the curative method of dosing is used in the latter instead of the prophylactic. The radiographic method is, of course, much the quicker and more animals can be used for each test. The authors also consider that the chief variations in the sensitivity of a stock fed on a supposedly constant diet are due to some factor other than vitamin D.

The method of bone analysis (with prophylactic dosing) is considered in greater detail by E. M. Hume, M. Pickersgill and M. M. Gaffikin.[32] The linear relationship between percentage of ash in the bones and the logarithm of the dose is only observed when eight or more animals are used on each dose. The exact position of the line depends on the severity of the rickets developed by the animals. The increments for percentage ash are smaller in the less rachitic series of rats, so that the straight lines of the graphs tend to converge to the point 54 per cent ash and 5 units dose.

Analyses of the 'line' test have been carried out by K. M. Key, B. G. E. Morgan and R. S. Morgan,[33] whilst the former authors and K. H. Coward have examined the possibility of using the growth-promoting property of vitamin D in its quantitative determination.[34] Key and Morgan constructed curves relating degree of healing to dose given, using Dyer's scale to assess the degree of healing. This scale is similar to the radiographic scales but has only six stages. Different curves were obtained in accordance with the different degrees of rickets which may be developed by the animals of different experiments. It is recommended that three reference curves be constructed, for slight, moderate and severe rickets respectively, for use in the assay of preparations for their vitamin D potency. The curves were used in an examination of the effects of changing the ratio of calcium to phosphorus in Steenbock's rachitogenic diet: changing the ratio from 4 : 1 to 2 : 1 was equal in effect to a daily dose of 0·7 unit of vitamin D. A knowledge of the effects of changing this ratio may be required when it is necessary to test food materials containing these elements for their content of vitamin D. R. S. Morgan measured the area of calcification in the 'line' test with the planimeter and found that the degree of healing was strictly proportional to the logarithm of the dose between 0·125 and 1·0 unit. Doubling the dose increased the area of calcification by 59 sq. mm. using a magnification from line to drawing of 11 diameters. With 10 pairs of rats, the probable error of a test is ± 7 per cent: this is less than with the radiographic method since the error in the diagnosis of healing is eliminated. The chief source of error is the variable response of litter mates to a given dose.

It is of interest to note that Coward, Key and Morgan found that there is also a linear relationship between the growth response of rats and the logarithm of the dose given. The animals were kept on the standard vitamin A-free diet without vitamin D. Vitamin A was supplied in the form of carotene. The growth method gives the same results as the line test, but is more laborious and probably less accurate. The growth response to vitamin D is less than that to vitamin A on the same diet.

In conclusion, it may be mentioned that Prof. Drummond considered some of the illnesses which may result from a deficient intake of the different vitamins. It is difficult to estimate how far minor disorders may be due to this cause in Great Britain to-day. It would be of great interest to carry out a dietary survey, on the lines of previous surveys dealing with the protein, fat and carbohydrate intake, but investigating the consumption of vitamin-containing foods, so that the vitamin requirements of the population might be more accurately estimated.

Obituary

MR. C. F. BEADLES

CECIL FOWLER BEADLES, pathological curator of the Hunterian Museum at the Royal College of Surgeons, whose death at the age of sixty-six years occurred on January 3, received his medical education at University College and Hospital, London, where he gained honours in histology. In 1890 he obtained his diploma and afterwards passed two years as senior house surgeon at the Cancer Hospital; there he was enabled to perfect himself in microscopical technique and pursue the study of pathological anatomy, the branch of medical science towards which his natural inclination turned.

Mr. Beadles's subsequent career falls into three periods defined by the posts which he successively occupied, namely, those of assistant medical officer at the London County Asylum, Colney Hatch, assistant to Prof. Shattock, then curator of the Hunterian Museum, and finally pathological curator of the Museum. While at the London County Asylum, he was constantly engaged in scientific studies relating both to mental disease and to pathological anatomy generally. Most of his published works at this time were contributed to the *Transactions of the Pathological Society*, which contain no less than forty-five papers from his pen. He communicated a few papers to the Medico-Psychological Association, of which he was a member and from which he received a prize and bronze medal in 1894 for a dissertation on degenerative lesions of the arterial system in the insane. He interested himself particularly in the vascular supply of the brain, the anatomical variations and anomalies of which he considered might have a bearing on mental disease and on the clinical signs of such conditions as embolism.

The results of Mr. Beadles's researches in this direction were embodied in the Hunterian lecture which he delivered at the Royal College of Surgeons in 1907–8. He contemplated writing a book on the subject which should include the literature, and he collected a great number of extracts from British and foreign sources for this purpose. However, the War intervened and his subsequent ill-health prevented him from resuming the work.

In 1909 Mr. Beadles became assistant to Prof. Shattock, who was then engaged on the revision of the pathological catalogue of the Hunterian Museum, and he continued to be connected with the Museum up to the time of his death, a period of more than twenty years. At the outbreak of the War he was appointed, under Government, to deal with the pathological war material which was accumulated at the Royal College of Surgeons. This was an arduous undertaking involving the examination, preparation, and dissection of a vast number of specimens, their selection to form a fully illustrative series of the injuries and diseases incidental to warfare, their mounting and suitable display. The collection thus formed now constitutes a separate and important section of the Hunterian Museum, consisting of about three thousand specimens; and it will remain as a standing memorial to the honour of Mr. Beadles.

The final period of Mr. Beadles's career, that of the curatorship, is mainly one of steadily declining health. When he succeeded to Prof. Shattock in 1925 he was already afflicted with bronchial and pulmonary trouble. The commencement of this he considered to have dated from the time of his work on the war material, and it is quite possible that the inhalation of the vapour of formalin to which he was constantly exposed at that time was responsible for his illness, although his ill-health was aggravated by other complications. His untiring energy and devotion to museum work, however, did not desert him even to the end, although the work became an obvious burden.

Mr. Beadles was a pure pathological anatomist of a type now gradually disappearing amid the experimental tendencies of the time. He was entirely absorbed in his subject, beyond which he had but few interests, and he lived a life of absolute seclusion. The well-merited honour of the fellowship of the Royal College of Surgeons was conferred upon him shortly after his promotion to the curatorship.

PROF. R. DONALDSON

PROF. ROBERT DONALDSON was a man of very great culture. Before commencing his medical studies, he took an arts course in the University of Edinburgh and graduated M.A. in 1899. In 1904 he obtained his M.B., Ch.B., and the same year received the diploma in tropical medicine. He gained his fellowship of the Royal College of Surgeons of Edinburgh in 1908, the diploma of public health in 1912, and his M.D. degree with honours in 1918.

Donaldson commenced his pathological career as assistant with me in the University of Sheffield. From there he went as assistant to Prof. Walker Hall in the University of Bristol. Later he was appointed pathologist to the Royal Berkshire Hospital, Reading, where, during the War, he was specialist officer in charge of the laboratory. From Reading he went to St. George's Hospital as lecturer in pathology and in forensic medicine, and in 1928 he was appointed to the Sir William Dunn chair of pathology tenable at Guy's Hospital.

Dr. Donaldson took a very active part in research work, and his knowledge of modern languages was a great help to him. The mass of routine work which falls to the lot of a lecturer and professor in departments which are inadequately staffed—and this seemed always to be Donaldson's lot—limited his output of published work; but his knowledge of the subject which he taught—and he was a great teacher—is evidenced in his excellent book on morbid anatomy, of which the second edition appeared only last year.

Dr. Donaldson had wide interests outside his department. He was a Scot with all the keenness for knowledge which is so characteristic of his countrymen. He loved his native land, and he had a wide knowledge of its customs, its songs and its language. His wanderings in the Highlands and Islands inspired him to learn Gaelic. He was a man of deep religious convictions, and his home life was an inspiration to many. Those of us who knew him regarded him as a great pathologist and teacher, we welcomed him as a colleague, but we loved him as a man, and, as one of his greatest friends has said of him, "Allied to a keen analytical intellect was a heart of the warmest emotions". To his wife and his two daughters we tender our heartfelt sympathy.

J. M. BEATTIE.

DR. MALCOLM E. MACGREGOR

IT is with regret that we have to record the death at the early age of forty-three years of Dr. Malcolm Evan MacGregor, who was in charge of the Wellcome Entomological Field Laboratories at Esher, Surrey. Born in South Africa, he studied at Cambridge and later as a Carnegie fellow at Harvard, where he came under the influence of Dr. L. O. Howard, and decided to study the medical aspects of entomology. He first came into prominence during the War when he served with the R.A.M.C. in East Africa in connexion with mosquitoes and other insect carriers of disease. From East Africa he was invalided home, and on recovery was placed in charge of a War Office Research Laboratory at Sandwich to study mosquitoes in their relation to the spread of malaria in Great Britain from returned soldiers carrying the disease.

After the War, MacGregor took charge of the Entomological Field Laboratory founded by Sir Henry Wellcome. Here he continued his studies of mosquitoes, particularly with the view of solving some of the fundamental problems underlying their mode of life, feeding, hibernation and reproduction. For a period, these researches were interrupted by a visit to Mauritius on behalf of the Colonial Office, to study the mosquito-malaria problem. A valuable report was the result, and it was shown that a second important malaria-carrying mosquito occurred in Mauritius, namely, *Anopheles funesta*, which had been overlooked both by Sir Ronald Ross and Sir Andrew Balfour during their visits to the island.

On his return to England, MacGregor resumed his mosquito studies. He showed that the diverticulum, a sac which opens into the œsophagus of the mosquito, is a kind of reservoir into which the mosquito can direct at will or by reflex action fluids unsuitable for the stomach. He studied the extraordinary effect of ultra-violet rays on the larvæ, the various reactions of waters in which they occurred, and strove to establish the fact that the larvæ of culex and anopheles mosquitoes live in waters of different but particular hydrogen ion concentration. Latterly, he had been studying a so-called autochtonous race of *Culex pipiens*, a race which is able to complete its life-cycle without any blood meal and does not hibernate.

MacGregor's death at the height of his scientific career is nothing short of a tragedy, inflicting a serious loss upon the science of medical entomology. He was the author of numerous scientific papers dealing with the subjects of his particular study, and of a book entitled "Mosquito Surveys".

News and Views

Gold in Kenya and Native Reserves

THE memorandum issued by the Colonial Office on the position in Kenya in relation to the leasing of lands in native occupation on native reserves for mining purposes cannot be regarded as satisfactory. It affords no guarantee that the more objectionable consequences of the amendment of the Ordinance will not ensue. For example, while admitting that "the matter of immediate importance is to ensure that any individual native . . . shall receive compensation and an alternative piece of ground on which he may live and work in proximity to his market", it states that the Governor "does not contemplate any difficulty in providing individual dispossessed natives with land". But when the amendment was introduced, and also when it was discussed in the House of Commons, it was stated definitely that the reason for payment of a money compensation was that land could not be provided for all the natives who, it was anticipated, would be dispossessed. Nothing is said of the terms of tenure of the land on which the dispossessed natives will be settled, a matter of the first importance in tribal organisation, as has already been pointed out in NATURE.

THE Chief Native Commissioner himself, in introducing the amendment, stated that the natives would not lease their lands voluntarily and that their "most sacred traditions" would be violated by "removal from their own land on which they had the right to live, and setting them up on another piece, the owners of which had the right to eject them". No attempt is made to meet this difficulty. As the explanatory memorandum issued to natives had been circulated before the Chief Native Commissioner made his statement, it is therefore to be presumed that it did not assuage native feeling in this matter. Yet every anthropologist is well aware that it has been through neglect of susceptibilities of this character that our Colonial administrations have been involved in innumerable difficulties and even, in some instances, in native risings. The small area which may be required on any given holdings, and the temporary character of the exclusion, both points which are stressed, are irrelevant. There are other points in which the memorandum of the Colonial Office falls short in facing the difficulties of the situation. These cannot be discussed within the compass of a brief note; but it is evident that further deliberation is a vital necessity.

George Edwards, F.R.S.

AN illustrated article by Mr. T. E. James in the first quarterly issue of *Science Progress* for 1933 recalls the work and interests of George Edwards, an eighteenth century naturalist (1694-1773) and Copley medallist in 1750 of the Royal Society. Edwards was made library-keeper of the Royal College of Physicians in 1733, on the recommendation of Sir Hans Sloane, its president, remaining in office at Warwick Lane for thirty-six years. During that period he devoted himself to the portrayal in colour of birds, quadrupeds and fishes (mostly new to science) from actual specimens. The Linnean Society has recently received from Major V. Seymer a set of Edwards's works, containing annotations and memoranda by a contemporary and correspondent of Edwards, namely, Henry Seymer, of Hanford, Dorset. It may be of interest to mention that the Linnean Society already possessed copies of Edwards's works, these having originally belonged to Joseph Grote, a collector of rare books on natural history and botany. At his death in 1805, his brother inherited his property, and ultimately the books, with many fine engravings, passed into the ownership of George Grote, the historian. His widow gave the greater portion of the collections to University College, London. Mrs. Grote reserved, however, the works by Edwards, but in 1877 placed them at the disposal of Sir Joseph D. Hooker, whom she designated as "the worthy and distinguished president of the Royal Society". In the end, Sir Joseph gave the books to the Linnean Society.

Arthur Woolf, 1766–1837

ONE of the most interesting chapters in the history of the steam engine is that relating to the Cornish pumping engine. Early in the eighteenth century, Newcomen engines were installed for pumping at the Cornish mines, and in 1777 these began to be superseded by the low-pressure condensing engines of Boulton and Watt, which required much less coal. While the mines gained greatly by the use of the latter, the all-embracing patent of Boulton and Watt prevented other inventors from putting their ideas into practice. The expiry of this patent in 1800 was a boon to the whole county and through the work especially of Woolf and Trevithick, the pumping engine of the nineteenth century proved as superior to the Boulton and Watt engines as the latter had been superior to the Newcomen engines. Of Trevithick's work a great deal will be said at the forthcoming centenary celebrations, while of Woolf's work a review was given in a paper entitled "A Cornish Engineer, Arthur Woolf, 1766–1837", read to the Newcomen Society by Mr. Rhys Jenkins on January 18. The first great improvement due to Woolf and Trevithick was the use of steam pressures up to 40 lb. per sq. in., while Woolf was one of the pioneers of the compound engine. Like all their contemporaries, these engineers worked at a time when the caloric theory still held sway, and they were quite ignorant of the true theory of heat. Carnot, however, in his famous essay of 1824, referred to Trevithick and Woolf as being among the veritable creators of the steam engine, and it is as such they will be remembered.

British Science Guild Research and Development Lecture

THE Council of Management of the British Science Guild, at a meeting held on January 19 last, decided to establish an additional lecture to be known as the Research and Development Lecture. The main object of this annual lecture, which will be delivered in London in April or May, is to promote attention to the importance of research—both purely scientific and technical—and the utilisation of its results in the service of mankind. The increase of knowledge thus secured has direct relationship with industrial development, the daily needs of the community, economic principles and social problems, human welfare and progress as well as methods of thought and the trend of civilisation. Each lecturer will be asked to select from his own particular field suitable examples of contacts with any of these factors of progressive thought. In establishing the lecture, the British Science Guild associates it with the name of Sir Richard Gregory and his work as editor of NATURE in securing increased recognition for scientific work and scientific workers in national life and in international affairs. The first of these research and development lectures will be given in May by Sir Harold Carpenter on "Metals in Industry".

Papal Observatory in Castel Gandolfo

HIS HOLINESS POPE PIUS XI has shown himself a frequent patron of science. On the occasion of the official opening of the new academic year at the Papal Academy of Science, in the presence of the Pope, Dr. Joh. Stein, S.J., who has succeeded the late Father Hagen as director of the Papal Observatory, announced, as reported in the *Osservatore Romano* of December 19–20, that the Papal Observatory is to be moved from the Vatican to Castel Gandolfo, where it is to be rebuilt on a much larger scale. Castel Gandolfo is an old summer residence of the Popes, which has been returned to them by the Italian Government according to the terms of the Lateran Treaty and is being thoroughly restored. Joined to this historic building, a new observatory with the most modern equipment is to be constructed at the Pope's instructions, with easy access from the State apartments for his convenience during his summer visits to Castel Gandolfo. The contract for the supply of the instruments has been placed with Messrs. Carl Zeiss, Jena. The equipment includes two domes of about 8½ m. diameter, a large double astrograph with a 400 mm. refracting and a 600 mm. reflecting camera, a co-ordinate measuring apparatus, a spectrograph, several objective prisms, a Blink comparator and an astro-wedge-photometer, as well as a new refractor-mounting for an existing telescope objective. The domes will each be equipped with an observation platform of the latest type, the so-called tilting platform, which is moved by electric motors controlled by switches within easy reach of the observer. On these sliding platforms the observer can easily follow any movement of the telescopes. The instruments and apparatus are to be supplied within two years.

Crystals of the Living Body

THE first Friday evening discourse of the new session was delivered at the Royal Institution on January 20 by Sir William Bragg, who chose as his subject "The Crystals of the Living Body". Growth and purpose require directed arrangement of the protein or other molecules of which the body is made. The protein of a silk fibre is a long chain-like molecule consisting of a sort of backbone in which two carbon atoms and one nitrogen make the regularly recurring links, and this structure is common to the various forms of protein. Of every pair of carbon atoms one has, so to speak, a spare hook to which other atoms or strings of atoms may be attached, like pendants to the links of a mayor's chain. In the case of silk these pendants are very simple, consisting alternately of a hydrogen atom and a group containing one carbon and three hydrogens. The new methods of X-ray analysis enable us to prove the arrangement of these chains, and to measure the dimensions of the links. They show that the chains tend to group themselves into bundles, and they find the forms which the bundles take. This arrangement is obviously appropriate to the functions of the silk fibre, to its flexibility and its tenacity. The fibre is spun, in fact, just as we spin a rope on a far grosser scale, laying the vegetable fibres side by side. Such a parallelism is no surprise, for in all our examinations of organic substances in the laboratory, physical, chemical, or biological we have always found that our best practice is foreshadowed. A particularly interesting comparison can be made with the structure common to hair, wool, horn, feathers and the like. These are built on the same principle as the other proteins, from which they differ only in the nature of the pendants. The latter in this case attract each other strongly, and in drawing together give the chain a wavy or crumpled form : the process has lately been explained by Astbury. The in-curled proteins, with their internal attractions satisfied, are not susceptible to many reagents which bring about the dissolution of proteins of the extended form. Thus hair long outlasts other parts of the body in their decay.

Synthetic Sound Films

ACCORDING to a report in the *Times* of January 11, an interesting curiosity has been on exhibition in Germany in the form of a sound film "Die Tonënde Handschrift" in which the sound part was originally prepared without the use of sound. Details are not available but from the illustrations it appears that the film uses the contour method of sound recording in which a constant density of blackening is produced over varying widths of the film. Normally this is produced by light reflected on to the moving photographic film from an oscillograph operated by electric vibrations transformed from the original sound vibrations. Herr R. Pfenninger in the new process makes templates each containing several sound waves and photographs a reduced image of these in turn on to the stationary film. Both the preparation of the templates and their photographing naturally take much longer and the object is not to reproduce graphically the tones of well-known musical instruments but to construct music of new timbre. The report states that the laboriousness of preparing the templates is to be reduced by the use of a typewriter which uses wave-outlines instead of letters, a separate sound-wave typewriter being used for each timbre. It would be interesting to know if the characteristic wave-forms of singing or string playing of exceptionally good quality could be successfully copied so as to give reproductions of melodies which had not been actually performed. This might make possible the performance of a new musical work by the voice, or playing, of an artist no longer living.

Migration from and to Great Britain

A PAPER by Mr. H. Leak and Mr. T. Priday on the subject of migration from and to Great Britain was read at a meeting of the Royal Statistical Society on January 17. Factors affecting post-War migration, of which the chief are social insurance, national assistance to emigrants, and the United States quota system, were fully considered and also the main features of post-War migration, particularly in regard to the inter-censal period 1921–31. A comparison of pre-War and post-War migration shows that the annual average of the net outward movement of British subjects from the British Isles to places out of Europe was about 193,000 in the ten years 1904–13 and 112,000 in the years 1921–30. In 1931, however, there was a change from net emigration to net immigration, the excess inward in that year amounting to 37,000, while for 1932 the figure is estimated to be about 50,000. Although, in the future, emigration may be on a considerably smaller scale than in pre-War days, it may still, within the next one or two decades, be on a scale commensurate with the ability of Great Britain to release population of the ages which the Dominions require, regard being had to the diminishing numbers of new entrants into the labour market.

Anomalous Eskimo Vertebræ

SOME suggestive results, which may possibly turn out to have a bearing on the question of the existence of evolutionary tendencies in modern man, emerge from an examination by Dr. T. D. Stewart, of the Smithsonian Institution, Washington, D.C., of skeletal material brought back by one of the Institution's recent expeditions to Alaska. The material consists of some two hundred Eskimo skeletons, which were obtained by excavation. Dr. Stewart's observations point to the possibility that they may prove an exception to the generally accepted view that the human body has attained a high degree of specialisation, which shows little tendency to vary. Approximately 12 per cent of these Eskimo skeletons have 25, instead of the normal 24, presacral vertebræ. The anomaly is present in nearly sixteen per cent of the males, but in only less than one per cent of the females, and it is considerably more frequent in skeletons secured north of the Yukon. In a preliminary report on these results, which has been issued by the Smithsonian Institution, it is pointed out that this frequency is nearly twice as much as the maximum previously recorded among the northern Eskimo. Among Europeans it runs to only 3-6 per cent; but one study notes 7 per cent among the Japanese. In the material examined by Dr. Stewart, the tendency seems to be towards a lengthening of the spinal column from the sacrum. There is no variation in the cervical vertebræ to show a tendency towards the lengthening of the neck. The predominance of the anomaly among males is held to give some indication of a hereditary character. Dr. Stewart's material will appear in full in the *American Journal of Physical Anthropology*.

Research Work of the Metropolitan-Vickers Electrical Co. Ltd.

NOTWITHSTANDING the industrial depression the activities of the Research Department of Metropolitan-Vickers have not been in any way curtailed. The research on the properties of steel at high temperatures is being continued, particular attention being paid to an examination of the combined influence of time and temperature on the changes of physical properties. The investigations of carbon steels have raised difficult problems in connexion with carbide spheroidisation as well as the obscure phenomenon of embrittlement shown by some of them. The results already obtained have been useful in determining suitable working stresses in advance of present practice. The general problems of the corrosion of metals and methods for their protection have been under continuous investigation. Experiments have been made on the corrosion of aluminium alloys when in contact with beverages and food stuffs. The importance of studying engineering noise problems is shown by the fact that the acoustics laboratory has been more than doubled in size. Using the methods of continuous evacuation developed in the Metropolitan-Vickers laboratories, rapid progress has been made in the technique required for the production of high vacua and its many applications to engineering problems. An X-ray set specially adapted for studying engineering problems has been developed and standardised and is now on the market. Progress has been made in inventing methods of protecting zinc and zinc base alloys by means of electro-deposited coatings. Special solutions have been discovered for cleaning, pickling and plating base metals of this kind. Accelerated corrosion tests have been devised which enable the protective value of different thicknesses of deposit to be rapidly determined.

Tariff of Electricity Supply

THE Central Electricity Board in conjunction with the National Consultative Technical Committee has prepared a form of tariff laying down the principles under which electricity will be supplied directly to authorised undertakings. This form of tariff applies to the whole of the supply given to undertakings which do not own 'selected' stations. It applies also to that part of the supply to selected stations which they do not generate for themselves. The new tariff consists of three parts. The first is a service charge in respect of each point of connexion to the grid, the second a fixed annual power charge based on the maximum demand for power during the year at each point of connexion, and lastly, a running charge for each kilowatt hour supplied. No service charge is made for the first point of supply. The kilowatt charge is based on the maximum demand for the year. This maximum demand is taken to be twice the largest number of kilowatt hours supplied during any half-hour in the months of January, February, November and December. This tariff has been agreed with the District Committee for mid-east England and the central Scotland tariff will be decided shortly. The tariff system, although at first sight complicated, is based on sound principles and should prove practical. Various modifications have to be applied when the energy supplied is less than the product of the volts and amperes, that is, when the power factor of the load is low. The application of the Act has necessitated the evolution of instruments which will measure both kilowatts and kilovolt amperes respectively. Accurate instruments of this type are now available. It will be interesting to see the magnitude of the reductions in price to the consumer in mid-east England.

Restoration of Prosperity to Transport

AT the present time the industry of transport seems to be far from flourishing. In the aggregate, statistics show that road, rail, air and water transport are losing money. We welcome therefore the paper by W. Rees Jeffreys, chairman of the Roads Improvement Association, on transport problems of the Empire, which was read to the Royal Society of Arts on November 29. He takes a world-wide view of the whole problem, pointing out some of the causes of the depression and making many helpful suggestions. All forms of transport are the servants of the community. They serve trade and industry, and so long as they are serviceable they are entitled to a fair remuneration. They are not entitled to place a burden upon trade or industry by excessive charges or by dictating to the producer and the manufacturer what kind of transport he shall employ. Anti-road transport legislation within the Empire for the purpose of protecting State investments in railways has failed to bring prosperity to the railways concerned. Railway finance has often failed because it proceeded on the assumption that railways are permanent and can always be made profit-earning by regulating rates. In Great Britain, road finance has proceeded on sounder lines, as highway expenditure has been met largely out of current expenditure. The ill-conceived legislation which has introduced rigidity into railway rates, wages, hours and conditions of labour has hindered progress to recovery. Co-operation between all kinds of transport is necessary, and rigidity is fatal to it. The closing down of non-paying railways and their conversion into roads should be encouraged. In the discussion, Mr. C. Erlund stated that an enormous saving could be effected so far as goods are concerned, by electrifying several of the main-line railways. This makes electrification a far more attractive proposition than it appears in the Weir Report.

A Modern Japanese Power Station

SINCE the inception of the Kyushu Hydro-Electric Railway Co. Ltd. about twenty years ago, the policy of using steam power in Japan as distinct from hydro-electric power has thoroughly justified itself. A description is given of their new 50,000 kilowatt steam generating station, in the *Metropolitan Vickers Gazette* for October. It was completed in September 1931 having taken little more than a year to construct. The total cost of this station is much lower for its output than any station previously built in Japan. The main buildings are heavy steel structures designed with a view of resisting earthquakes and the walls of the building are of corrugated sheet steel. The chief coal supply is transported by land, the power station being quite close to the main railway line. Special arrangements have been made to minimise the labour and time involved in handling coal. The flue gases are thoroughly cleansed before emission into the air. The larger particles of grit are caught in mechanical collectors and the fine dust and fumes are washed by high-pressure water sprays. The molten slag is tapped from the furnaces, broken into fine pieces by strong water jets, and removed by pump sluicing. The two steam turbine generating sets having outputs of 25,000 kw. at 11,000 volts were made by the Metropolitan-Vickers Electrical Co. Ltd. Electroflo steam instruments are used and Kent, Negretti, Siemens, Kelvin, Cambridge and Bailey boiler instruments have been installed. It is interesting to notice that power is transmitted to a substation at 22,000 volts by cables of the Emanueli oil-filled type, paper insulated with a double sheathing of lead.

Fur-bearing Animals in Michigan

REFERENCE to some results of Dr. Ned Dearborn's investigation into the food of predatory fur-bearing animals in Michigan has already been made in these columns (Dec. 17, 1932, p. 905). The pamphlet (52 pp.) in which the results appear, initiates, with the title of *Bulletin I*, a series of publications by the School of Forestry and Conservation in the University of Michigan, which will contain for the most part the results of studies by the Bureau of Forest Research. Conditions as regards the fur-bearing animals have changed much since the early days of colonisation, and although Michigan still ranks third amongst the States in fur production, the destruction of the forests—hard-woods and soft-woods in the north, nut-trees in the south—and the draining of the swamps, have vastly reduced the numbers of fur-bearers. It is said that the numbers are not half what they were twenty-five years ago; even the weasel (*Mustela noveboracensis*) is no longer common in many localities, and the only upland fur-bearer which has held its own is the skunk. It may seem strange that while in Britain we are engaged in a war of extermination against that new invader, the musk-rat, Dr. Dearborn should regret its disappearance with the draining of Michigan marshes for agricultural purposes. He says that in some cases marshes are now more profitable for the musk-rat fur they produce than they would be for agriculture if drained, and cites the case of a drained marsh near Athens in Calhoun County which to-day is said to be worth no more than a single crop of musk-rats would be were it still undrained. "As matters now stand," he writes, "it behoves the owners of marshes to consider well before attempting to drain them". Other conditions, other advice!

Preservation of Fossil Bones

THE difficulty of preserving fossil bones found in deposits of the later phases of the Ice Age or more recent beds is known to collectors and museum curators; often enough the bones crumble to dust after a night's exposure to the air. Much can be done by immediate attention to preserve such relics for examination and permanent exhibition, and a paper on the "Bakelite Impregnation of Fossil Bones" by H. W. Nichols and Phil C. Orr, of the Field Museum of Natural History in Chicago, ought to be widely known (*Museums J.*, vol. 32, p. 47, May 1932). In the Field Museum, most of the older impregnating materials have been tried, paraffin, glue, gum arabic, shellac, wolfite and several mastics. In some respects these are all deficient. Of the older materials, shellac was found to be the most satisfactory, but Dr. Case's bakelite process is better than any other. Broken bones are cemented with a mixture of plaster of Paris and dextrin, and when the cement is dry, the bone is placed on a screen and lowered gently into a tank of bakelite reduced to a suitable condition of fluidity by the addition of bakelite thinner. The bones thus treated are allowed to dry and the surface cleaned. The greater number of bones require no further treatment, but if a specially strong surface is required the bones may be baked at a temperature of about 208° F. or more, when the bakelite, undergoing polymerisation, gains full strength and becomes no longer soluble in the thinning solution.

Dr. Arnold Berliner

A SPECIAL issue of *Die Naturwissenschaften* for December 16 celebrates the seventieth birthday on December 26 of its founder and editor, Dr. Arnold Berliner. It extends to 73 pages, includes scientific contributions from more than forty authors and a frontispiece portrait of Dr. Berliner. Prof. Einstein in a short note recounts how twenty years ago Dr. Berliner saw that a periodical was wanted in Germany which would give accurate information on all branches of science and thus enable research workers in special fields to form their own opinions of advances in other fields. That his periodical has succeeded so well in this object is due to the catholicity of his interests and to his insistence that his contributors should express themselves in concise and clear language which could be understood by non-specialists. His fights to secure well written articles led him to say that a scientific author should be "a cross between a mimosa and a porcupine".

Spread of Influenza

According to Science Service, Washington, D.C., the influenza epidemic appeared to have reached its height in the United States at the end of December; for the week ended December 24, 123,138 cases were reported to the United States Public Health Service. In England and Wales a large increase in the number of deaths from influenza is shown in the Registrar-General's return for the week ended January 14, the figures being 1,041, compared with 681 the previous week. Greater London was the worst affected area, though considerable outbreaks are reported in many parts of the country.

Wensleydale Earthquake

Father J. P. Rowland, S.J., has given in the *Times* of January 21 his determination of the epicentre of the earthquake of January 14. The records at six observatories, from Stonyhurst (34 miles) to Oxford (187 miles), agree fairly well with a position half a mile to the north-east of Hawes Junction and a time at the origin of 8h. 30m. 20s., G.M.T. The shock was also observed at Felton in Northumberland, 70 miles from the above epicentre.

Cerebro-Spinal Meningitis

The period of the highest incidence of cerebro-spinal fever in Great Britain is approaching and it is clearly desirable to secure accurate observation on the efficiency and potency of all the serums in use. Since the most valuable test of the efficiency and potency of serums is clinical and it rarely happens that any one hospital has sufficient cases for useful differential study, the Ministry of Health is now endeavouring by means of individual case inquiry to collect and examine all evidence on serum treatment and the co-operation of medical officers of health, hospital medical officers and medical practitioners is invited. Forms for the purpose can be obtained on application to the Senior Medical Officer, Med. I., Ministry of Health, Whitehall, S.W.1.

Guide to the British Pharmacopœia

The British Drug Houses, Ltd., Graham Street, City Road, London, N.1, have issued a "B. D. H. Guide to the B. P. 1932", which will be of use to all who are interested in drugs, chemicals, galenical preparations, and the standards of the new British Pharmacopœia. The volume contains xvi + 122 pages, and, like the similar guide to the British Pharmacopœia of 1914 (of which a few copies are still available), is published at 2*s.* 6*d.* It is pointed out that the new "B. P." contains 128 articles and preparations which become official for the first time; while there are 357 deletions. Special attention is directed in the Guide to the former, and to innovations and alterations in general.

Announcements

Mr. Ll. B. Atkinson, a past president of the Institution of Electrical Engineers, has been elected an honorary member of the Institution.

The annual congress of the South-Eastern Union of Scientific Societies will be held at Norwich on June 7–10, under the presidency of Prof. E. J. Salisbury, Quain professor of botany at University College, London. Further particulars can be obtained from the secretary, Mr. Edward A. Martin, 14 High View Close, London, S.E.19.

The following have been elected officers of the Royal Microscopical Society for the present session: *President:* Mr. Conrad Beck; *Hon. Treasurer:* Mr. C. F. Hill; *Hon. Secretaries:* Mr. J. E. Barnard and Prof. R. T. Hewlett; *New Members of Council:* Dr. E. Hindle, Dr. J. E. McCartney, Mr. E. K. Maxwell, Mr. J. Rheinberg, and Mr. E. A. Robins.

The inquiry organised by the Inter-Parliamentary Union of Geneva and published in 1931 by P. S. King and Son, Ltd., at 16*s.*, under the title "What Would be the Character of a New War?" has been re-issued by Victor Gollancz, Ltd., at 5*s. net*. The original publication was reviewed at length in Nature of February 13, 1932 (p. 219).

Applications are invited for the following appointments, on or before the dates mentioned:—A member of the scientific staff of the Radio Research Station, Slough—The Secretary, Department of Scientific and Industrial Research, 16, Old Queen Street, Westminster, S.W.1 (Jan. 30). Assistant civil engineers for the Civil Engineer-in-Chief's Department, Admiralty and H.M. Naval Establishments—The Civil Engineer-in-Chief, Admiralty, London, S.W.1 (Feb. 18). A male assistant superintendent of traffic in the London Telephone Service and a male assistant traffic superintendent in the provinces, General Post Office—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1 (March 2). A technical assistant in the Directorate of Technical Development, Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants. A research assistant in mycology in the Department of Agriculture, University of Cambridge—The Secretary, School of Agriculture, Cambridge.

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A New Impulse Generator for Three Million Volts

OF recent years considerable attention has been focused on the behaviour of insulation under electrical stresses of very short duration. The importance of these studies need not be emphasised; suffice it to say that investigations in conjunction with the cathode ray oscillograph on all forms of insulating material at fairly low voltages and on all forms of assembled electrical high-tension apparatus at high voltages have still to be made, as the information at present available is of the most meagre nature.

These studies are very important, because every time an electrical circuit is made or broken a transient is propagated, and in addition, lightning is responsible for the occurrence of transients of large magnitude in exposed circuits, such as overhead transmission lines. In the laboratory, low voltage transients are easily produced, but the apparatus required for the generation of high voltage transients has hitherto been very bulky on account of the large clearances which are necessary between all the active parts of the generator. To extend the scope of our investigations with higher voltage transients would necessitate buildings of enormous dimensions, and the object of this note is to indicate how such requirements can be obviated.

The circuit most commonly used for the generation of transients comprises essentially a condenser and a spark gap. For high-voltage impulses, it is not economical to construct a condenser to withstand the full required impulse voltage between the poles, and recourse is therefore made to a number of lower-voltage condensers connected in series. These may be charged in parallel with a voltage V and discharged in series, a voltage nV being thus generated, where n is the number of condensers. The switching over from parallel to series connexion is performed by spark gaps. When suitably constructed, these spark gaps are known to break down in times of the order of 10^{-7} sec., so that a generator having many condenser and spark gap stages can still produce a transient of very steep wave front.

An obvious method of reducing the size of the generator is to immerse the whole of the apparatus in a medium of higher electric strength than air, for example, in oil. Unfortunately, the time lag of breakdown of the spark gap is thereby considerably increased, and the rate of rise of voltage of a multi-stage impulse generator is therefore very seriously diminished. Furthermore, the gas bubbles and carbon liberated in the spark gaps are undesirable features, and the energy absorbed in the gaps greatly reduces the efficiency of the generator. By the removal of the spark gaps from the oil chamber containing the condensers, most of the economy in dimensions gained by the use of the oil container is sacrificed, and difficult bushing problems are introduced.

It has been found that in air the time lag of a sphere spark gap decreases with increasing air pressure, while it is well known that for small spacings the air pressure/breakdown voltage curve of the sphere spark gap is approximately linear. Here we have the exact requirements for a compact, oil-immersed impulse generator capable of producing transients of steep wave front. If all the spark gaps are segregated into a column of air at high pressure, the compact features of the oil-immersed generator are preserved together with the advantageous electrical features of spark gaps operating in a gaseous instead of a liquid medium. On these principles, we have constructed an impulse generator capable of delivering 3 million volts in an oil container 5 ft. in diameter and only 10 ft. in height. The condensers are of the oil impregnated type and are all charged in parallel through resistance columns arranged vertically in the cylindrical container. Connexions from each condenser are taken to the spark gaps, arranged also in a vertical column in a tube immersed in the same oil chamber and under a pressure of many atmospheres of air. Only the low voltage connexions to the condensers and the lead carrying the full impulse voltage appear outside the oil container, as even the potential divider for connexion to the cathode ray oscillograph is incorporated in the same oil tank, and is therefore of very small linear dimensions.

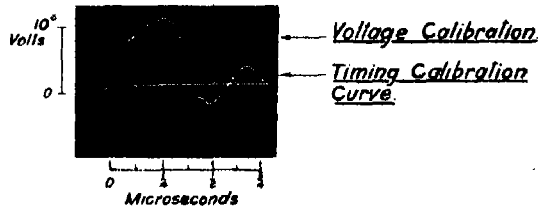

FIG. 1.

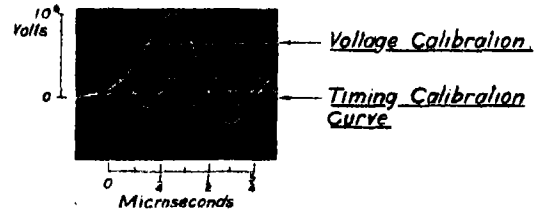

FIG. 2.

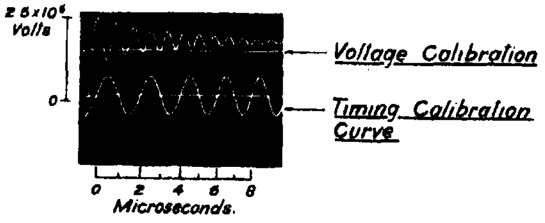

FIG. 3.

Figs. 1 and 2 illustrate the effect of air pressure on the steepness of the wave front of the transient, the rate of rise at atmospheric pressure (Fig. 1) being 3000 kv./μ sec., while at a pressure of 3 atmospheres (Fig. 2) this has increased to 4800 kv./μ sec.

The transient was applied to a sphere gap set for about 1000 kv. and the oscillograms show the very short time lag before breakdown of the gap.

Fig. 3 shows the open circuit wave of the generator operating at approximately 2500 kv. The rate of rise of voltage is 6000 kv./μ sec., and a time of 200 μ sec. elapses before the voltage has fallen to half its maximum value. The oscillations can of course be removed by the introduction of an appropriate resistance into the circuit.

Our thanks are due to Mr. H. C. Thompson for help in the construction of the apparatus, to Messrs. W. G. Hawley and R. V. Whelpton for their assistance with the cathode ray oscillograph, and to Mr. A. P. M. Fleming for permission to publish this note.

Energy of Cosmic Rays

IN NATURE for September 3, 1932, p. 364, I published the curve of the intensity of cosmic radiation in the high atmosphere, deduced from measurements made with a self-registering electrometer. It was possible by extrapolation to find the intensity I_∞ of radiation at its entrance in the atmosphere. The preliminary value given has now been corrected by the experimental determination of the factor which reduces the measurements with the ionisation chamber at 5 atmospheres to 1 atmosphere. Now the value I_∞ is found corresponding to a production of 333 pairs of ions cm.$^{-3}$ sec.$^{-1}$ in air at 0° and 760 mm. mercury pressure.

The graphical integration of the curve, giving the ionisation as a function of the height, makes it possible to calculate the total number of ions, produced by total absorption of cosmic rays by a column of air of 1 sq. cm. section. The high value of $1{\cdot}02 \times 10^8$ pairs of ions is found. Some time ago, Millikan and Cameron[1] made a similar calculation, which gave a value of only $1{\cdot}28 \times 10^7$ pairs of ions, due to an insufficient knowledge of the intensity in the high atmosphere. Taking the energy required to produce a pair of ions in air[2] as 32 electron-volts the flux S of energy coming to the earth from the cosmic rays is found to be $5{\cdot}2 \times 10^{-3}$ erg. cm.$^{-2}$ sec.$^{-1}$.

From an astrophysical point of view, the great energy of cosmic rays is remarkable. A body which absorbs all the cosmic rays would be heated by them. Equilibrium will be attained when the absorbed flux S of cosmic rays is equal to the heat radiation σT^4 of that body. T works out as 3·1° Kelvin. The value is equal to the temperature (3·18°) which Eddington[3] finds for a black body heated only by the heat and light radiation of stars. Eddington's calculation relates to a point in our local system of stars, but not in the neighbourhood of one of them. If at such a point the flux of energy of cosmic radiation is equal to that on the earth, the temperature of a black body, absorbing entirely the *two* radiations, rises only to 3·7° Kelvin, according to the T^4 law. But at a point in space among the spiral nebulæ, the ordinary radiation is very small and causes only a very small rise of temperature. Supposing that cosmic rays originate in such intergalactic space, they would produce an elevation of temperature corresponding to the flux of cosmic rays.

A more detailed report will be published shortly in the *Zeitschrift für Physik.*

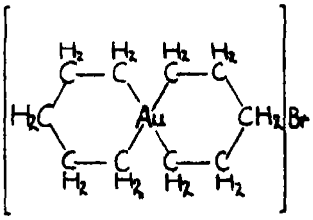
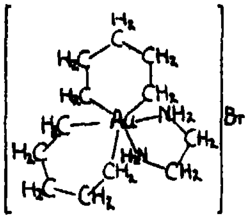
Organic Compounds of Gold

THE reaction between hydrobromoauric acid and magnesium pentamethylene bromide in ethereal solution proceeds somewhat differently than with the simpler magnesium alkyl bromides[1]. A colourless, crystalline, sparingly soluble salt is obtained which must be *spiro*bis(pentamethylene)gold bromide (i).



(i)



(ii)

This compound has been identified through its ethylenediamine derivative, ethylenediamino*spiro*bis-(pentamethylene)gold bromide (ii), which is a fairly stable colourless crystalline salt having a greater solubility in water than compound (i).

These compounds present several points of interest. In (i), the gold atom, as in many gold compounds, is 4-covalent with an octet of electrons and it is significant that a gold atom attached to four carbon atoms can function as a cation. In (ii) the gold atom is 6-covalent, and while gold compounds have been described in which the gold atom is 6-covalent, they are very few. Further, since the groups attached to the gold atom must have an octahedral configuration, compound (ii) should be capable of being resolved into optically active isomers. This is the first compound to be described in which a configuration of groups attached to a gold atom permits of this possibility.

The investigation indicated is being continued and extended in various directions. The small amounts of these organic gold compounds obtained at present in any one reaction which takes at least two weeks is only one of the factors which explain the slow progress of the work.

Iodoacetic Acid, Glutathione and Tissue Glyoxalase

DUDLEY[1] has shown that the action of tissue extracts in converting methyl glyoxal to lactic acid, or phenyl glyoxal to mandelic acid, is inhibited by iodoacetic acid. Lohmann[2] considers, however, that this is probably not the cause of the poisoning action of iodoacetate on animal tissues, since, in the case of the crude extracts used, a much higher concentration of iodoacetate was needed than that required to stop glycolysis.

Quite recently Lohmann[3] has made the important discovery that reduced glutathione can function as a co-enzyme to methyl glyoxalase deprived of its activity by dialysis. Working either with such extracts of rat liver purified by isoelectric precipitation of much of the protein and by dialysis, or with undialysed extracts, I find that the action of iodoacetic acid in arresting glyoxalase activity is completely reversed by the addition of reduced glutathione to the inhibited extract. The reaction occurs at once even in the presence of a ten-fold excess of the inhibitant, and clearly shows that the action of iodoacetate does not involve irreversible destruction of the enzyme itself. Further, in a dialysed extract activated by a known amount of glutathione, the quantity of iodoacetate required to stop lactic acid formation is approximately equivalent to the glutathione added to that extract. Thus the powerful activity of the purified extract, conditioned by the presence of added glutathione in 10^{-4} to 3×10^{-5} molar concentration, is rapidly retarded or inhibited by iodoacetic acid in the same molecular concentration.

On the other hand, the glyoxalase activity of the crude extract is quite unaffected by this concentration of iodoacetate; it must be increased about a hundredfold in order to arrest or retard the lactic acid formation. The behaviour of fresh liver slices, studied by Warburg's method, I find much more nearly corresponds with that of the purified extracts; with concentrations of iodoacetate down to $1 \cdot 5 – 5 \times 10^{-4}$ molar, the inhibition of glyoxalase action is well marked, and here also the activity is immediately restored by the addition of reduced glutathione (10^{-3} molar) to the contents of the vessels.

These results suggest the occurrence of a direct interaction between glutathione and iodoacetic acid; and this has in fact been observed. If dilute neutral solutions of iodoacetic acid and purified glutathione are mixed, a vigorous reaction occurs in which acid (HI) is liberated and the sulphydryl group of the glutathione is attacked. The progress of the reaction is followed by mixing the bicarbonate solutions of the two reactants in an atmosphere of nitrogen and carbon dioxide (*p*H of solution 7·4) and measuring manometrically the carbon dioxide evolution due to acid production. It is then found that for each molecule of reactant decomposed one equivalent of acid is set free; the kinetics and chemistry of this reaction are now being further investigated.

How far the other actions of iodoacetate may be referred to a similar mechanism, or to oxidative reactions in the way suggested by Waldschmidt-Leitz and Schäffner[4] and by Bersin[5] is not yet clear.

Structural Formulæ of the Chlorophylls

SOMEWHAT more than a year ago, a structural formula for chlorophyll-*a* was suggested[1] in which a carbomethoxy residue was placed in the β-position of one pyrrole ring. This seemed necessary as a monomethyl ester (phæopurpurin 7) was obtained as one of the products of an oxidative hydrolysis ('phase test') and the position of the methoxyl group in this phæopurpurin was clearly established. We have now found that the purest samples of the phæophorbides of the 'a' series do not yield any phæopurpurin 7. Under special conditions of oxidative hydrolysis, a monomethyl compound can be isolated (as the sole product) and the carbomethoxy group in this substance can be shown to be part of the side chain attached to the bridge (the so-called γ-position). This finding is in accord with the position of the methoxyl group in Fischer's formula for chlorophyll-*a*.

We have found in the mother liquors from the purification of the phæophorbides, considerable quantities of a material very similar to the normal members of the 'a' series but which on oxidative hydrolysis yields phæopurpurin 7 (a monomethyl ester). The presence of this material in our original samples was thus responsible for the phæopurpurin 7 which we obtained. It is difficult to separate this substance from phæophorbide-*a*, which it appears to resemble closely in physical and chemical properties. There seems no escape from the conclusion that we are dealing with a substance very similar to phæophorbide-*a*, but differing in the position of the methoxyl group. The oxidative hydrolysis of crude chlorophyll or of chlorophyllides has shown that a precursor of phæopurpurin 7 is present to the extent of 1–5 per cent in a variety of plants. The mother liquors from crystalline ethyl chlorophyllides from *Datura* contain as much as 20 per cent. It would appear that there are two forms of chlorophyll-*a*, and we are now engaged in an attempt to isolate in a pure state the second form (or the corresponding chlorophyllide). There are some indications that a similar situation exists in regard to chlorophyll-*b*, but there has been no definite evidence as yet published establishing the position of the methoxyl group in the 'b' series.

If there are two very similar forms of chlorophyll-*a*, differing only in the position of a methoxyl group, a formula must be found which allows of the interchange of the methoxyl group between two potential carboxyl groups without serious structural modification. This interchange must involve the carboxyl group of the pyrrole ring and that of the bridge. The lactam formula, which we mentioned previously[2] as an alternative of our anhydride formula, satisfies these requirements; the anhydride formula does not, nor do the formulæ containing a carbocyclic ring connecting the pyrrole nucleus and the bridge.

The analyses of the pure phæophorbides present a difficulty as we have realised for many months, and has recently been emphasised by Stoll[3] and Fischer[4]. We are strongly inclined to the opinion that on isolating and drying the crystalline compounds, water is lost, leaving an unsaturated grouping which then adds water again in solution, regenerating the hydroxy compound.

A more detailed discussion of the structural formulæ of chlorophyll-*a* and -*b* will be given in a series of papers to be published shortly.

'Raw' Weather

I EXPECT that Sir Leonard Hill's remarks in NATURE of January 7 (p. 28) on this subject go a long way towards answering the inquiry about the physiological effects of raw weather, but I doubt if they cover the case of deep-seated pain to bedridden rheumatic people. Yet such people are sometimes very sensitive to climatic conditions, so sensitive indeed that some of them will predict a change in weather unfailingly. They will tell you they can feel it in their bones and it may be, with people so situated, that actual changes in humidity or temperature can scarcely be invoked as causative factors, that they are directly susceptible to barometric fluctuations.

The suggestion might be checked if a group were willing to allow the experimentalist to subject them to slight variations in pressure.

Barnato Joel Laboratories, **SIDNEY RUSS.**
Middlesex Hospital.
Jan. 7.

IN his letter dealing with 'raw' weather, Dr. Dobson[1] has raised a question of considerable human interest which will probably require the combined experience of physicists and physiologists for its solution.

One explanation has already been mooted by Sir Leonard Hill[2], but apparently rests on the misapprehension that: "Cold moist air has a much higher conductivity than cold dry air." Reference to the "International Critical Tables" shows that, so far as information relating to the thermal conductivity of water vapour is available, this is not likely to be the case. At 46° C. the conductivity of water vapour is 12 per cent less than that of dry air, and there is no apparent reason why it should be greater at lower temperatures. It is difficult to imagine, therefore, how the admixture of a comparatively small proportion of water vapour with air could result in an *increased* thermal conductivity of the mixture.

Although the explanation of 'rawness' based upon the effect of moisture in the atmosphere appears to be untenable, it may be that the moisture content of clothing is important. There is evidence that even a small quantity of water adsorbed on the fibres of a textile material causes a considerable reduction in its insulating efficiency. Cold weather in England—at any rate in the south-eastern part of it—is usually dry enough to allow free transpiration of water vapour through the clothing. In 'raw' weather, however, the water excreted by the skin is retained in the clothing, with consequent feelings of chill and discomfort.

Another physical condition which may prove significant is the ionic content of the atmosphere. Work now proceeding on the Continent and in the United States[3, 4, 5] indicates that this factor, which is very variable, can produce remarkable physiological effects. In a cold environment the feeling of 'rawness' may well be one of them.

Molecular Fluorescence of Antimony

WE have obtained a rather strong fluorescence of diatomic vapour of antimony illuminated by a mercury arc of high luminosity; the temperature was about 950° C. and the pressure corresponded to a temperature of about 650° C.

There are four mercury lines which certainly excite a resonance spectrum and two other probable ones; the results are given in the accompanying table.

	Exciting Hg lines	No. of negative terms.	No. of positive terms
Certain	2967 A.	1	18
	3022	2	11
	3126	2	6
	3132	4	7
Probable	2925·5	1	1
	3342	1	5

The frequencies of the resonance terms can be accounted for by the equation

$$\nu = \nu_0 - 277\,(v'' + \tfrac{1}{2}) + 0{\cdot}68\,(v'' + \tfrac{1}{2})^2$$

Details of the investigation will be published shortly in *Bull. Soc. Roy. Sci.*, Liège, Belgium.

University, Liège.

Absorption of Light in Cæsium Vapour

WE have measured the absorption of light in cæsium vapour, by photographic photometry, from the series limit (λ 3184 A.) to λ 1935 A. The absorption cell was a quartz tube two metres in length. The vapour was superheated to about 270° C. and the vapour pressure was varied from 0·15 mm. to 0·6 mm.

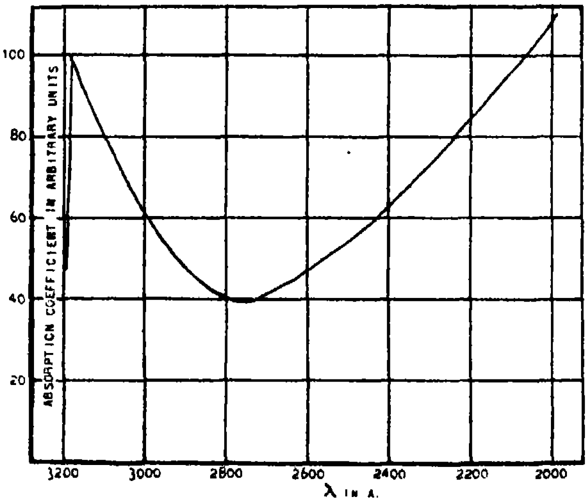

FIG. 1.

The absorption at any one wave-length appears to be directly proportional to the pressure, and the variation with wave-length is shown in Fig. 1.

The results may be compared with those obtained for the photo-ionisation of cæsium vapour[1, 2, 3, 4]. Mohler and Boeckner[1] made absolute measurements of the photo-ionisation for λ 3130 A. and obtained a value corresponding to an atomic absorption coefficient of 1·85 × 10^{-19} cm.$^{-1}$. Our experiments give, as a preliminary value[5] for the total absorption at the same wave-length 1·92 (± 0·1) × 10^{-19} cm.$^{-1}$. These agree within the limits of error and indicate that the whole absorption at this wave-length is photo-electric.

The form of the curve agrees more closely with the curve obtained by Little[3] and by Cooke[4] than with that obtained by the other workers[1, 2]. The rise in the absorption in the far ultra-violet is interesting and difficult to explain. We made special experiments which verified that this absorption is proportional to the vapour pressure. It therefore appears to be an atomic phenomenon.

We hope to complete the experiments and to publish a full account shortly.

Reversal of the Current from a Cuprous Oxide Photo Cell in Red Light

WHILE testing the sensitivity of photo cells of the rectifier type for various wave-lengths, we have observed a small reverse current with a cell of the 'Serpidox' make exposed to red light. As we have seen no reference to this effect, a few details may be worth noting. The cell is a commercial form of that described by M. Auger, the cuprous oxide film being covered with a thin conducting film, which we believe to be of gold. Contact is made with the latter by a metal ring, the inner edge of which forms the rim of the pupil, 17 mm. in diameter.

The inverse effect is irregularly distributed over the cell, as was shown by successively illuminating various areas, each about 4 mm. in diameter, with a beam of light of wave-lengths between 6070 A. and 6270 A. For a region some 5–6 mm. square, not quite central in the pupil, the current obtained was in the same direction as that for green, blue, or white light. For all other parts of the disc a varying negative response was obtained. Illumination of the metal rim is not necessary for the inverse effect, a relatively large negative response being obtained from a region near the centre. On the average, however, the central part of this cell gives a positive, and the marginal a negative response, the net effect of the whole cell being negative for this light.

The following figures indicate the behaviour of the cell for yellow and red light, λ being the mean wave-length of the light, and S_1 and S_2 the sensitivities of the central and marginal regions, respectively, expressed as percentages of the maximum sensitivities, which, in each case, occurred near 5,000 A.

λ (in A.)	5840	5940	6060	6170	6280	6380	6480
S_1 (per cent)	51·1	36·4	23·2	7·5	2·8	0·1	0·05
S_2 (per cent)	58·4	39·4	16·7	−5·0	−10·6	−7·1	−1·9

For longer wave-lengths to the end of the visible spectrum, S_1 was zero and S_2 had small negative values.

A cell made, and kindly presented to us, by M. Auger showed the inverse effect to a very slight extent. A second 'Serpidox' cell mounted in one of our marine photometers gave a reverse current when covered with a Schott und Gen. *R.G.*1 or *R.G.5*, or a Wratten No. 88 red filter and exposed to daylight in the laboratory. No reverse effect could be detected with a Siemens cell, which had a relative sensitivity about + 1·4 per cent at 6380 A. In this cell the conducting film is of silver.

As the current flowing in the external circuit of any of the above cells under the influence of white light is from the copper back to the transparent film, it would seem probable that it is due to a front surface effect of the cuprous oxide film, the back surface being screened by the opacity of the film. If we assume that red light penetrates the thinner parts of the oxide film in the Serpidox and Auger cells to such an extent as to cause the back surface effect to preponderate, we obtain at once an explanation of the patchy nature of the red reversal.

As an alternative explanation, we might attribute the reversal to the presence of cupric oxide, which Athanasiu has shown to give a reverse E.M.F.[1] As the cupric oxide, unlike the cuprous, is sensitive to wave-lengths greater than 6500 A., he obtained a reversal with a mixed oxide photo-voltaic cell in red light.

The possibility of such an effect occurring in these cells is obviously of importance if they are used to compare illuminations of different colours.

Twisted Trees

To one who has long been working on the problems presented by twisting (spiral grain) in trees, the suggestion made by Dr. Copisarow[1] that the phenomenon may be traced back to the mineral constituents of the cells, comes as a further possibility calling for examination in light of the facts so far as they have been recorded. Knorr's article in the *Journal of Heredity*, which was noticed by NATURE in the issue of July 23 (p. 136), 1932, and called forth the suggestion now under consideration, was apparently written without reference to the existing literature, even American literature, and leaves the reader with the impression that a new field was being examined for the first time, whereas it has attracted attention for at least a century.

Dr. Copisarow uses Knorr's data showing right- and left-handed twist to be approximately equally frequent as an argument in support of his suggestion, whereas the typical mode of occurrence is for either right- or left-handed twist to predominate strongly according to the species concerned. In certain species of pines in Europe and India, almost a hundred per cent of the trees over extensive areas may exhibit definite left-handed twist without a single example of right-handed twist. A change over in the individual from left-handed in youth to right-handed later in life is a fairly common phenomenon, recorded, for example, by McCarthy in America for *Picea rubra*. The mode of occurrence of twist often suggests that the soil may be the cause, but, at least in *Pinus longifolia*, twist may be equally prevalent on limestone with a deep clay loam soil, as on mica schist with sandy loam or on coarse granitic gneiss. Knorr's observation is significant that of several species, all liable to twist, perhaps only one would be found to be twisted in a given area, and another in a second area.

Twist in trees certainly appears to originate during the secondary growth of the stems and there are indications that the so-called sliding growth of the tracheids in conifers may be intimately connected with the development of an increasingly inclined slant to the grain of the wood. Further knowledge on the growth of wood elements from the cambial initials is required to enable us to understand exactly what happens, knowledge to which Prof. Priestley's studies in Leeds are making important contributions.

Unless Dr. Copisarow can develop his suggestion so that it will account for twist predominantly in one direction or another irrespective of soil, and for a change over in direction with time, it does not take us much further than my own made in 1925, that such a detail as the prevalent direction of circulation of the cell contents (if they do circulate at all) might decide the initial direction, and sliding growth might accumulate small inclinations (if the tracheids do slide or anything like it).

Spectrum of γ Cassiopeiæ

SINCE photography was first applied for recording the spectrum of this bright star, its spectrum has always been considered to be of a constant character. In 1928, I announced that a slight change had taken place, and since then I have made numerous observations which completely corroborate its variability. The relative intensities of the bright components of the hydrogen lines in the latter half of 1931 were such that the red components were a little brighter than the violet components. Since then, the violet components have been steadily increasing in intensity, and now (January) they are very much stronger than the red components, so much so that, in the case of $H\epsilon$ and $H\zeta$, the red components are scarcely visible while the violet components are quite strong.

A detailed discussion of all my observations since 1921, which include more than sixty photographs, will be published at a later date.

Heterogony and the Chemical Ground-Plan of Animal Growth

IN his letter in NATURE of December 3, Dr. J. Needham suggested that "the chemical ground-plan [of development] must be thought of as deformable in space-time". In this connexion, the deformations which are obtained by a change in the unit of time measurement seem to be particularly interesting. Needham showed that if we have two animals a and b and measure in each of them several chemical magnitudes M_a, M_b, N_a, N_b, etc., such as fat content, dry weight, etc., we find relations of the type $\log M_a/M_{a_0} = k \log N_a$ and $\log M_b/M_{b_0} = k \log N_b$ where M_{a_0}, M_{b_0} are specific constants and k is a general constant relating M and N for all animals. Now M and N are also functions of the time t. If we have $\log M_a/M_{a_0} = F(t)$ and $\log M_b/M_{b_0} = F(t)$ we can clearly choose another variable p such that $F(p) = f(t)$. That is to say, by choosing a suitable unit for the measurement of time, we can convert the growth curve of M_b into that of M_a: and further, the same system of time measurement will convert all the growth curves of chemical magnitudes of animal b into those of animal a, provided only that in each case there is the linear relation between the logarithms, with the general constant k which Needham discovered. Thus we could regard the two systems of time measurement defined by t and p as the relative time scales of chemical development of the two animals.

Such relative time scales may become very interesting when data are available for comparing them with relative developmental time scales derived in other ways. The relative time scales of morphological development can be obtained fairly easily. Now it has been shown in various cases that the morphological stage at which an organ becomes embryologically determined may vary widely in nearly related species. These two criteria, namely, stages of morphological development and times of determination of different organs, should provide two other systems of relative time measurements. It would be very interesting to know how these two are related to one another and to the time scales of chemical development.

The Constant of Gravitation, *G*.

IT appears that before the advent of the theory of relativity the constant of gravitation was purely empirical. No theoretical estimate or discussion of it has at any rate come to my notice. It is perhaps worth while to obtain a theoretical explanation of the constant, even from the point of view of Newtonian gravitation, in view of the remarkable success of the latter in the regions of space that have already been explored. Following Mach, one expects that the constant G should be dependent upon the distribution of matter in the entire universe: it may be explained in terms of the other universal constants of relativistic cosmology.

Suppose that the total matter in the universe is distributed at random in a sphere of radius R where the boundary condition is furnished by corpuscular radiation going round with the velocity C. Then, according to Newton,

$$MG/R^2 = C^2/R \text{ or } MG/C^2 = R,$$

where M is the total mass in the universe. We may compare with this the relativistic formula

$$M^+ G/C^2 = (\pi/4)R \text{ for the Einstein world.}$$

There are two reasons why M and M^+ should differ slightly as they do; first, in estimating M^+ the entire mass is supposed to be at rest, which is far from the truth, and secondly, there is the mathematical difficulty of measurement pointed out by Painlevé[1].

Research Items

Excavations at Kuala Selinsing, Perak. Mr. Ivor H. N. Evans, having carried out further excavations on the Tanjong Rawa site, Kuala Selinsing, Perak, Malay Peninsula, has now summarised his conclusions in an account of this later work (*J. Fed. Malay States Museums*, vol. 15, pt. 3). The inhabitants were not Mohammedans, and were traders in beads of semi-precious stones and glass. Some of these were of local manufacture. The stone beads probably came from India; others show affinities with Borneo and Sarawak, and with ancient beads found among Kachins and Chins, these in the latter instance being derived ultimately from both China and India, sources with which the Selinsing people may have been in touch. A piece of yellow lead slag may point to a connexion with the southern Shan States. The beads from Kuala Selinsing belong to a late iron age to early porcelain age culture that existed in India, the Malay Peninsula, Borneo and the Philippines. The people were almost certainly Hindus, as a definitely Hindu type of gold object has been found in the lower layer of the excavations; while a cornelian seal with a Pallava inscription (one of the most remarkable objects found in Malayan excavations in recent years) points to a connexion with southern India. The village would appear to have been built originally over the water, but accumulations of household refuse produced an island above the level of the highest tides. Burials took place under or among the houses, the bodies being placed in canoes and broken porcelain strewn over them. There are many types of pottery, mostly wheel-made with patterns akin to ancient Korean and Chinese. The settlement appears to have come to a violent end soon after A.D. 960, a date indicated by the presence of celadon wares. The earliest date suggested for the seal is about A.D. 400, but it was not found in the lowest level and may have been treasured for hundreds of years after the date of its manufacture, or perhaps be a survival of a script obsolete in India.

Shamans and Spiritism on the Mosquito Coast, Honduras. In an ethnographical survey of the Miskito and Sumu Indians of Honduras and Nicaragua (Bull. 106, Bureau of American Ethnology), Dr. Eduard Conzemius describes religious manifestations which have appeared among these peoples within the last forty years. These Indians are inhabitants of the tract of land once familiar under the name of the Mosquito Coast. The Miskito, who number about 15,000, are largely mixed with negro blood, as they intermarry freely with foreigners and assimilate all races readily. The Sumu, on the other hand, are exclusive. They number about 3,000 only and are decreasing. Many of the tribes, of which the names are preserved, have died out. Their language has many variants, some of which are mutually unintelligible. The shamans play a great part in the lives of these peoples, acting as medicine-men, doctors, augurs, rain-makers, conjurors, wizards, and the like. Their opinions carry great weight in tribal assemblies. According to tradition, their art was introduced from the east by a white man. The Sumu have only one class of medicine man, the sukya, whose office is hereditary. Nearly every village has its sukya. Among the Miskito, however, there is also a higher type, the okuli; but of these there should not be more than one at a time. He is a special representative of the Thunder God, and controls the elements. The new movement in religious manifestations is not unlike the nyalism of the Jamaican negro. It is a form of possession which seizes on the people when they are engaged in earnest prayer. They claim that they then have no control over their movements, which are due to the presence of the Holy Ghost. They are believed to be able to cure the sick by the laying on of hands, and to have revelations from God during their dreams. Obeah, brought from Africa by slaves, still exists.

Spread of the Great Crested Grebe in Britain. A very thorough collection of information relating to the great crested grebe in Britain has been made by T. H. Harrisson and P. A. D. Hollom with the help of 1,300 collaborators, and this together with the analysis of the data makes a most important account of the history of the species (*British Birds*, Aug. to Nov., 1932). In 1860, following a period of slaughter for the sake of the feathers, only about 42 pairs were left in England; but a continuous and progressively rapid increase has raised the number in 1931 to about 1,154–1,161 breeding pairs and a total population of some 2,650 adults. The spread has in general been from east to west, and there can be no doubt that the Wild Birds Protection Acts of 1880 and earlier have been a main factor in the increase, although the fact that increases have also occurred on the Continent points to a widespread influence. There too, however, increasing protection by law has to be reckoned with. In spite of protection, human interference is still the main cause of recorded deaths (36 per cent). The authors have estimated that a pair of grebes and their young consume 300–630 lb. of fish in the course of a summer; which gives a total fish consumption from England and Wales of 900,000 lb. a year. A careful analysis is made of mortality factors, and it is pointed out that the habits of covering the eggs when the nest is left and of carrying the chicks upon the back have been important acquisitions in reducing mortality from the attacks of egg-eating birds and of pike.

New British Copepod. Mr. D. J. Scourfield has discovered at Tenby a new species of *Cyclops* which he describes in a paper entitled "A New Species of *Cyclops* found on the Cliff-face at Tenby (*Cyclops* (*Bryocyclops*) *demetiensis*, sp.n.)" (*Ann. and Mag. Nat. Hist.*, ser. 10, vol. 10, p. 559, December 1932). It is an event of importance when British copepods new to science are found because this group is one of the best known. The present species was found, at first one specimen only, in some wet greenish earthy material from a spot on the cliff-face of the North Bay at Tenby, Pembrokeshire, where a minute trickle of water came oozing out of a small fissure in the rocks. Later on, further specimens were found in the same place but where there was a slight admixture of moss. Only this one restricted locality yielded the copepods. This find is specially interesting because all other known *Bryocyclops* are tropical, coming from Java and the New Hebrides, living in wet moss, cups formed by the leaves of plants or in empty coconut shells. Mr. Scourfield is of the opinion that his new species is not truly a moss-dweller but rather that its true habitat is in the fissures in the rocks. *Cyclops* (*Bryocyclops*) *demetiensis* is a pretty little copepod with a peculiar eye of very unusual form surrounded by a mass of black granules in three parts, one dorsal and two lateral. It is possible that the form of the eye may have something to do with its mode of life in dark places. It is an active swimmer. Although no ovisacs were seen, a few nauplii were discovered in the bottle containing the copepods. These nauplii showed a separation of the eye parts which is very characteristic.

Mites of Fruit Trees. Literature dealing with the mites attacking fruit trees is not very accessible to the general horticulturalist, so that a lengthy synopsis by Mr. A. M. Massee is very acceptable (*J. Pomol. and Hort. Sci.*, vol. 10, No. 2, 1932, pp. 106–129, "Some Injurious and Beneficial Mites on Top and Soft Fruits".) The mites are dealt with according to the trees they attack, and apples, pears, plums and damsons, cherries, peaches, nectarines and apricots, nuts, walnuts, quinces, currants, gooseberries, raspberries, blackberries and strawberries are mentioned. It is interesting to note that there are several beneficial mites which are either predaceous, like the red velvet mite of apples which feeds on woolly aphis or they may feed on moss and lichen, as the flat scarlet mite (*Tenuipalpus glaber*) or the beetle mite (*Euzetes lapidarius*). The control methods which are given for the injurious species include many new treatments and it is interesting to note that the application of tar distillate winter washes is not an unmixed blessing, for it kills off many beneficial mites.

Inheritance of Flower-Size. There are very few published studies showing how flower-size is inherited in crosses between species with large or small flowers. The memorial volume to the late Prof. Jurius Philiptschenko (*Bull. Lab. Genetics, Leningrad*, No. 9.) contains a paper on this subject by Prof. Ruggles Gates. He has tabulated some thousands of measurements of petal length in four generations of hybrids descended from *Œnothera novæ-scotiæ* × a strain of *Œrubricalyx*. The former species has a mean petal length of about 12 mm., and the latter about 36 mm. This applies to flowers on the main stem. Those on the lateral branches always fluctuate about a mean 2 4 mm. less. The mean petal length of the F_1 hybrids was 18 mm., thus showing incomplete dominance of the small flower. Later generations showed striking segregation in flower-size, the modes for different plants of one culture ranging from 17 mm. to 30 mm. The number of factors for flower-size involved has not been determined, but must be two or perhaps more. Heterozygous plants, which will produce some larger flowered descendants, can be recognised since they show an exceptionally wide range of fluctuation which is generally bimodal. The segregants may breed true or they may again segregate. By tabulating the daily measurements from pure strains, the graphs of fluctuating flower-size can be compared with the changing meteorological conditions. In this way it is shown that a correlation exists between mean flower-size and the weather conditions on the day the flowers opened.

Earthquake Series at Nagusa, Japan. Messrs. A. Imamura, T. Kodaira and H. Imamura have described what they call an "earthquake-swarm" at and near Nagusa on the west coast of the Kii peninsula (*Earthq. Res. Inst. Bull.*, 10, 636–647; 1932). At Wakayama, which lies about three miles to the north of this district, the average number of sensible earthquakes recorded each year from 1911 to 1919 was 14. In 1920, the number rose to 104, increasing to 299 in 1923, and then declining to 142 in 1927. At Hikata, close to the central area, the total number of shocks in the swarm was 934. In May 1929, a network of seismological stations was arranged around the central area, and, from the records obtained at them, the positions of 91 origins were determined. The shocks were all local, few of them were felt more than 12 miles from the centre, and only two or three of the strongest cracked plaster or threw down stone fences. The shocks originated at various places within an area of about twelve miles in diameter in Wakaura Bay, and at depths that seldom exceeded 2½ miles. Two series of levellings along the west coast of the Kii peninsula, separated by an interval of thirty years, reveal a marked change in the level of the land. A block, about six miles wide, from Wakayama to Siotu, has bulged upwards. The maximum uplift is only 3½ in., but the summit of the dome is occupied by a fault along which most of the earthquakes occurred. The uplift is due to lateral pressure acting from north and south, and, with a persistence of the pressure, may end in a fracture. As the Kii peninsula has been the seat of devastating convulsions in the past (for example, in 1854), it is obvious that these earthquakes, weak though they may now be, require careful study.

Earth-Magnetic Effect and the Corpuscular Nature of (Cosmic) Ultra-Radiation. In an important paper with this title (Part 4), read by Prof. J. Clay before the Amsterdam Academy of Sciences on December 17 last, an account is given of a valuable series of observations on the intensity of the cosmic rays, made for him by Dr. J. Berlage on a vessel proceeding from Genoa to Batavia. The ionisation chamber filled with 22 litres of carbon dioxide at a pressure of 11 atmospheres was maintained at 130 volts, and shielded by 13 cm. of iron. The integrated ionisation current during each hour was registered photographically, using an electrometer. The results show a marked decrease from the Amsterdam value ($I = 1{\cdot}83$) to Genoa (1·75), and thence to the magnetic equator (1·56), with a small subsequent rise to Batavia and Bandoeng (about 1·62). Combining these with other recent results, Clay concludes that I is nearly constant from the poles to about magnetic latitude 46° (Amsterdam), and decreases by 16 per cent from there to the magnetic equator. He infers from this and other evidence, which he reviews, that the cosmic rays are corpuscular, having a Maxwellian energy distribution at the hardest end, with a mean energy of 3×10^{10} volts, which is cut off at the lower limit of 4×10^{9} volts by the atmosphere; he attributes the reduction of intensity below about 50° magnetic latitude to the exclusion from this region (according to Størmer's theory) of the less hard components of the radiation. This view implies that the hardness of the observed rays should increase towards the equator, and he quotes observations in support of this.

Relativity of Time. An experiment has been carried out by Kennedy and Thorndike (*Phys. Rev.*, Nov. 1) to verify directly the restricted relativity expression for time in a moving system. Homogeneous light is split into two pencils which traverse paths of different length and are then allowed to interfere.

Assuming the null result of the Michelson-Morley experiment, it is possible to show that the phase relationship of the interfering systems depends on the translational velocity of the system unless the time is given by the Lorentz-Einstein transformation. The experiment therefore consists in building a very stable interferometer and observing the fringes at different parts of the sidereal day, the circumferential velocity of the earth being alternately added to and subtracted from the motion of the solar system in the universe. The interferometer was built entirely of fused silica and was kept in a vacuum in a constant temperature bath. The 5461 line of mercury was excited in a special lamp to give very homogeneous light and a path difference of about 30 cm. was used. Special methods were used to measure the photographs of the interference pattern to 1/1,000 of a fringe. The result showed that the relativity expression was verified, provided that the velocity of the solar system is not less than a few kilometres per second. The apparatus was found to be stable enough to enable comparisons to be made over an interval of six months and thus to utilise the orbital velocity of the earth; and here it was found that an effectively null result was obtained. Since internebular velocities run in thousands of kilometres a second, this is interpreted as meaning that time—as measured by the radiation from a mercury atom—varies according to the Lorentz-Einstein law.

Hæmocyanin of *Octopus vulgaris*. Svedberg and Eriksson (*J. Amer. Chem. Soc.*, Dec. 1932) have determined the molecular weight of the hæmocyanin of *Octopus vulgaris*, the chemical and physicochemical properties of which have been much investigated. The sedimentation method was used and it was found that solutions of the crystallised hæmocyanin contained two constituents, for one of which (called *B*) the sedimentation constant varied strongly with the hydrogen-ion concentration of the solution whilst the sedimentation constant of the other is independent of hydrogen-ion concentration. This second component, called *Ao*-hæmocyanin, is regarded as a definite molecular species, like the hæmocyanins of snails (*Helix*, *Limulus*) previously investigated. It has a molecular weight of about two million, thus resembling the other hæmocyanins, and differing markedly from other proteins. The molecule is not spherical in shape. The molecular weight is the same in the oxygenated and in the reduced state. The results show that the *A* and *B* components are not two different proteins but represent two different kinds of aggregation in equilibrium, the change from *A* to *B* being reversible. This peculiar behaviour with regard to its dependence on hydrogen ion concentration is without parallel in the other proteins so far investigated by the ultracentrifuge method. The hæmocyanin from octopus gave a titration curve with three inflection points, one at pH 4·8, the isoelectric point, one at 6·3 and one at 7·5, the first two being characterised by great change in hydrogen ion concentration when the amount of acid or alkali present is but slightly changed.

Astronomical Topics

Astronomical Notes for February. Jupiter, Mars and Neptune are all near opposition, and are observable for most of the night. The northern hemisphere of Mars is turned towards us; this is less well known than the southern hemisphere, being turned to us at aphelion oppositions. The diameter of Mars increases during February from 12″ to nearly 14″. There is an eclipse of Jupiter IV on February 12; the disappearance is at 8.11 P.M. when Jupiter will be too low; but the re-appearance at 11.54 P.M. is observable. Two stars in the Pleiades are occulted by the moon on February 3, disappearing at 8.43 and 9.34 P.M.

Minima of Algol occur conveniently for observation on February 17 at 11.24 P.M. and February 20 at 8.18 P.M. It should be noted that the times in the B.A.A. Handbook are one day too great from February 18 until the end of April. Mira Ceti reaches maximum towards the end of February, and should be watched; it is only observable very early in the night. Its magnitude at maximum is subject to fluctuations, so comparisons with other stars are useful.

February and March are the best months for observing the zodiacal light in the evening; it should be looked for along the ecliptic as soon as it is dark when the moon is absent.

The central line of the annular eclipse of February 24 crosses Africa; a small partial eclipse is visible in southern Sicily and Greece.

Tidal Shifts in the Earth's Crust. Dr. Hecker announced about twenty years ago that the crust of the earth has tides of a few feet in height. Drs. H. T. Stetson and A. L. Loomis suggested the existence of a much larger shift in a paper read at the recent meeting of the American Astronomical Society at Atlantic City. They have discussed the differences between the time-signals distributed by wireless from the leading observatories of Europe and America, and find discordances between them that are considerably larger than the probable errors of observation. If the whole discordance be ascribed to an actual change in the distance between Europe and America, it would correspond to an oscillation of 63 feet every 12 hours. They also note that the time of transmission of the wireless waves is longer than the light-time for the distance, nearly in the ratio of two to one; they infer that the waves travel by a zigzag route, with about thirty reflections between the Heaviside layer and the surface of the earth or ocean.

Stars of the μ-Cephei Type. Mr. W. Zessewitsch, of Leningrad University Observatory, has sent a note dealing with the double periodicity of stars of the above type. He tabulates for nine stars of the type the shorter period P, the longer period M, the ratio M/P and the logarithm of P. From these data he deduces the following empirical relation between M and P:

$$M/P = 80{\cdot}2 - 44{\cdot}5 \log P + 6{\cdot}7 (\log P)^2.$$

P ranges from 16·5 days to 907 days; M from 600 to 6,200. The above equation gives sufficiently small residuals to suggest that some such equation exists between the two periods. He states that stars of the RR Lyræ type give a similar formula and expresses the hope that it will give a clue to the nature of the pulsations.

Air Waves from Experimental Explosions

By Dr. F. J. W. Whipple, Superintendent of Kew Observatory

IN the article in NATURE of December 31, p. 1008, with regard to the Oldebroek explosions of December 15, it was mentioned that a number of observations had been received at Kew Observatory. The observations have now been scrutinised with the object of arriving at a definite answer to the question whether the waves from the explosions were received in England.

The observations have been put in three classes. Those in Class A were made at such times as were consistent with the passage of the air waves with the normal velocity of sound along the ground or with a delay not exceeding five minutes. The observations placed in Class B were those which were too early or considerably too late, whilst those in Class C were made at such times that there was evidently no connexion with the explosions. There were 12 observations in class A and 10 in Class B. minutes after 6.0. At Farnham (normal time 24·3 minutes) a door gave a short sharp rattle at approximately 6.30 and again at 7.30, that is, 24 minutes after 6.6 and after 7.6. At Arundel (normal time 24·3 minutes) there was a violent rattle of a sash window but the estimate of the time, 6.30, is very rough. At Lymington (normal time 27·7 minutes) a window gave a clear thud at 28 minutes after 7.6.

Observers at Nuneaton and Maidenhead may possibly have heard sounds with the same trajectory as infra-sonic waves. On the other hand, sounds reported at Maldon, Cleethorpes and Boar's Hill, if coming from Oldebroek, were delayed by at least two minutes. In itself that is not improbable, but in view of the facts that none of the three observers in question heard more than one of the four explosions, that another observer at Boar's Hill reported that he could hear nothing and that noises of all sorts are only too common in England, these observations must be regarded as somewhat doubtful.

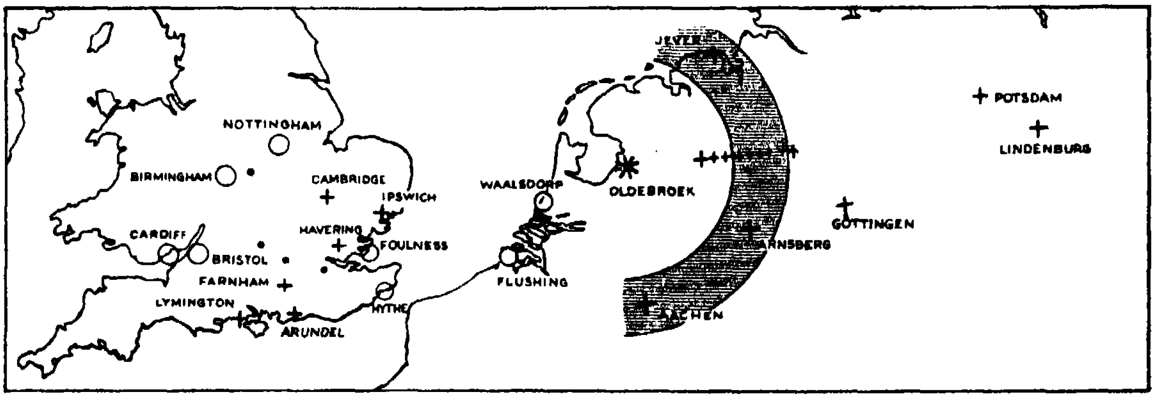

FIG. 1. Sketch map showing places where observations were made on the Oldebroek explosions of December 15, 1932.

+ On the Continent, received by undographs; in England, some evidence of reception of infra-sonic waves.
○ On the Continent, not received by undographs; in England, not recorded by hot-wire microphones.
● Sounds heard *at appropriate times*—Cleethorpes, Nuneaton, Oxford, Maldon, Maidenhead and South Croydon.

Six of the twelve observations falling in Class A refer to secondary sounds such as the rattling of windows. The agreement of these observations with the normal time of passage of air waves is very good. The most satisfactory observations are those at Cambridge. The normal time (reckoned at 3 seconds per kilometre) for waves from Oldebroek to Cambridge is 20·2 minutes. The times that elapsed between the explosions at 6.0, 6.6 and 7.6 and the observations at Cambridge were 21¼, 20½ and 20½ minutes respectively. As the observer noted the first of these receptions when she was awakened by the vibrating motion of the window, a mistake of a minute is not unlikely.

Confirmation by the observations at Ipswich, Havering-atte-Bower, Farnham, Arundel and Lymington indicates that there was a large area over which the aerial disturbance was appreciable. This area lies between the microphone stations at Hythe and Foulness and those at Nottingham, Birmingham, Cardiff and Bristol. It is known now that at none of these stations could the air waves be detected.

At Ipswich (normal time 16·5 min.) a lady felt her bed quiver and heard a faint rumble 16¼ minutes after 6.6. At Havering-atte-Bower (normal time 20·3 minutes) birds were disturbed between 19 and 22

The reception of the air waves at Cambridge at the time appropriate for normal transmission is remarkable. The condition which favours the passage of air waves westwards close to the ground or sea is the presence of east wind, increasing in strength with increasing height, or alternatively, west wind decreasing with increasing height. On December 15, however, the wind was from south-west and moderately strong. Unfortunately, there was much low cloud and no information is available as to the wind at a greater height than 600 metres; at that height the velocity at Felixstowe was about 15 m./s. It is not impossible that the wind fell off rapidly above the lower cloud and that the air wave was therefore able to travel westwards at a moderate height.

On the other hand, the possibility that air waves travelled very rapidly westwards at a great height, so rapidly that the time lost in ascent and descent was compensated, must not be overlooked.

It has been realised since the War that in this part of the world the sounds of explosions produced at points far to the east at distances of 200 km. or more are likely to be heard in summer but not in winter. Accordingly, it may be anticipated that if the Oldebroek experiment is repeated at some time during the coming summer, more positive and therefore more interesting results will be obtained.

I should like to take this opportunity to thank all correspondents who kindly communicated their observations and also to express my appreciation of the trouble taken by the observers who manned all the microphone stations which were in operation.

A preliminary report on the observations made on the Continent has been circulated by Prof. H. Hergesell, president of the International Commission for the Investigation of the Free Atmosphere. Of the German stations provided with undographs close to the direct line from Oldebroek towards Lindenberg, those at distances of 105, 136, 155, 161, 170, 183, 190, 198, 201, 213 and 225 km. were successful in obtaining records of the air waves, as were the stations at Aachen, Arnsberg, Jever, Lindenberg, Göttingen and Potsdam. No waves could be recognised on the undograph records in Holland.

Observations of audibility show an abnormal zone which has, in Germany, a mean radius of 145 km. and a maximum of 215 km. This zone extends to eastern Belgium. The inner zone of normal audibility was narrow; there was some extension to the east, as was to be expected from the prevalence of west wind.

That the air waves were received at places to the east of Oldebroek and not at the principal English stations to the west is in accordance with expectation, as is the fact that there was abnormal audibility in the eastern part of Belgium (south of the source) but not in the western part (south-west of the source). The very small inner radius of the outer zone of reception of air waves, 105 km., is also typical of winter observations. The reception of air waves at Cambridge and other places in England was unexpected and therefore, if the evidence is accepted, all the more interesting.

It is understood that the experimental explosions which were to have taken place in Novaya Zemlya on the same morning as the Oldebroek ones had to be postponed.

Similar experiments, organised by Dr. Bruno Rolf, were to be inaugurated in Sweden on January 11 by the explosion of 300 kgm. of guncotton near Boden. Five undographs provided by the International Meteorological Association were to be used for the first time on this occasion.

British Industries Fair

SCIENTIFIC INSTRUMENT SECTION

THE Scientific Instrument Section of the British Industries Fair will again be situated in the Grand Hall at Olympia. Of the 14,500 sq. ft. of space to be occupied by this section of exhibitors, nearly a quarter will be taken up by the composite exhibit of a group of British scientific instrument manufacturers who have co-operated for this purpose. The whole of the exhibits may roughly be divided into two categories, namely, (*a*) technical instruments and apparatus, such as are used for control and testing in works, for laboratory research or for the teaching of science in colleges and schools; (*b*) scientific instruments of a more or less domestic character, such as barometers and thermometers. A very wide field of scientific instruments will thus be covered, ranging from a simple pocket magnifying lens to the equipment required for the most refined micro-photographic work.

Among the new, improved, or adapted products of the instrument industry, about which advance information is available, the following may be mentioned. James Swift and Son, Ltd., will exhibit Nicol and other polarising prisms such as are used in the latest apparatus for television and picture transmission. A new model of the tintometer, very light and portable, and enabling rapid measurements to be made, will be shown by The Tintometer Ltd. This instrument enables the specification or definition of colour to be made in terms of reproducible units or standards, in the form of graduated and numbered glass slides. A stereo-prism binocular, with an extra wide field, a magnification of 7 diameters, and a 50 mm. object-glass, having a light-transmitting power very greatly in excess of that of any prism binocular previously made, will be one of the exhibits of Ross Ltd. Among other products, W. Watson and Sons, Ltd., will show a new low-power microscope for the rapid examination of specimens varying in thickness from 1 mm. to 6 in. This firm's exhibits will also include a special microscope 'for crime detection' and a new form of photometer for the measurement of the comparative densities of photographic plates and for the measurement of reflections from papers and other materials. This last instrument makes use of a photoelectric cell with a suitable magnifying system.

The Foster Instrument Company is exhibiting at the Birmingham Section and, besides a complete range of automatic temperature controllers, will show a 'Blackie Heat-Loss Gauge'. This last named instrument, it is claimed, is the only known instrument of its kind, and, since it is directly calibrated in B.T.U's / sq. ft. / H.R., it can be used even by unskilled operators.

Thermometers reading to an extremely high degree of precision—for example, to the nearest 0·005° C.—for use in research and industrial work will also be among the exhibits at Olympia.

Another noteworthy exhibit will be the projection microscope to be shown by Vickers. It is designed primarily for the purposes of metallography, and will deal with specimens up to 50 lb. in weight and enable magnifications varying from 3 to 5,000 diameters to be obtained. The apparatus will, as desired, provide for visual observations, or take photomicrographs or project the images on to a screen for demonstration purposes. The Cooke optical comparator is designed for the quick and accurate comparison of machine parts produced in quantities. It is intended to supersede the use of high and low limit gauges in works' inspection departments. A total magnification of 1,000 is achieved by means of a system of mechanical and optical levers, and a variation of 0·0001 in. from the standard can be detected. An instrument for observing the precise character of the movement of any rotating or oscillating part of a machine or apparatus is the 'Whidbourne' stroboscope. By means of this instrument—to take one example—gear wheels can be observed in motion without having to stop the machine. The observer, on looking through the stroboscope, sees the gear wheels apparently stationary, and can thus readily detect any defects. Analytical balances will be shown which, it is claimed, will at least equal, if not surpass, the corresponding foreign balances which were widely used until a few years ago. In these balances the beam is made of an alloy having a negligible coefficient of expansion. One special balance has been designed for the estimation of moisture in tea, tobacco, flour and other materials.

Of the various instruments and apparatus used for instructional purposes in schools and colleges, mention may be made of the 'Simplex' ripple projector which throws on to a screen images of wave forms and motions, the ripples being produced in a glass trough by means of an electro-magnetic vibrator. This instrument enables experiments to be made showing, for example, the effect of sound in rooms and halls of various shapes.

Of the numerous other exhibits that will be on view in the Scientific Instrument Section of the Fair we have space merely to mention the 'Stormoguide', an instrument designed to 'forecast' the weather, and two popular British-made cameras at low prices—one fitted with an anastigmat 3·5 lens at 75*s*., and the other a 3¼ in. × 2¼ in. box camera at 6*s*. 6*d*.—the lowest priced camera, it is claimed, on the market.

Altogether, the visitor will find scientific exhibits of abundant interest at Olympia.

Prevention of Roof Falls in Mines

DURING the early years of the Safety in Mines Research Board in Great Britain, the staff recruited consisted almost exclusively of chemists with no actual mining experience. Their energies were directed towards chemical aspects of the safety problem, and in particular to the phenomena of explosions, a study which lends itself readily to laboratory investigation. Calamitous as gas or dust explosions may be, the reports of the Secretary for Mines show that they normally account for only about five per cent of the total fatal accidents occurring annually in the coal mines of Great Britain, whereas the fatalities caused by falls of roof or sides account for approximately fifty per cent. Thus whilst explosions create most public interest in the safety of mines, falls of roof and sides cause by far the most casualties.

The activities of the 'Safety in Mines' movement have now been extended to include a co-ordinated research on the causes of falls of roof and their prevention. In consequence of the great variation in mining conditions, these investigations are being carried out in all the important coalfields of Great Britain. They are under the direct supervision of committees consisting of leading mining engineers in the respective areas. Progress reports are circulated periodically. The North of England Institute of Mining Engineers (Support of Workings in Mines Committee) has just issued a pamphlet, "Safety in Bord and Pillar Whole Workings", for free circulation among all concerned. The 'bord and pillar' method of mining, that is, dividing a coal seam into a system of large squares or blocks ('pillars') by first developing narrow roadways (called 'bords' and 'walls') and afterwards extracting the coal left in the 'pillars', is extensively adopted in the Northumberland and Durham coalfields. The factors involved in the movement of the overlying strata when driving the narrow roadways are discussed together with the best methods of controlling the roof movements. Measurements have shown that the rate of roof movement is greatest closely adjacent to the working face and, hence, the necessity of effectively supporting this critical area so as to reduce the danger of fracture of the roof with consequent falls is stressed by the Committee.

In addition to the circulation of this pamphlet a cinematographic film has been made showing a system of coal-getting at a Northumberland colliery where the methods of roof support advocated are now in use. This film is to be exhibited throughout the northern coalfield.

Fatigue Limit of Medium Carbon Steel

IT has been known for some time that iron undergoes several small changes at temperatures between that of the room and say, 350° C. These changes can be detected by variations in several physical properties and also appear to have some influence on the mechanical properties of the material. So far, however, no attempt has been made to investigate any effect of these change points on the fatigue limit of the metal. A paper by Mr. J. W. Cuthbertson, read before the September meeting of the Iron and Steel Institute, endeavours with considerable success to fill this gap in our knowledge. He has shown that the fatigue limit of a medium carbon steel rises as the temperature is increased to about 90° C. It then falls very rapidly, and at 120° C. or thereabouts, is less than at room temperature, to what degree, however, is still unsettled. As the temperature is still further increased the fatigue limit rises again very rapidly and at about 190° C. is some three tons per square inch higher than at room temperature. A second rapid drop then ensues, and a minimum occurs at about 220° C. followed by a further small rise. In an atmosphere of nitrogen the increase is progressive up to at any rate 350° C., but in air the fatigue limit begins to fall when the temperature exceeds about 300° C. The marked depression around 120° C. particularly is an observation of very great interest.

The paper, further, is of importance in connexion with the general measurement of fatigue limits. One method which has been suggested for their rapid determination is to plot the load deflection curve which, at first a straight line, shows a change in direction when the fatigue limit is attained. The method, however, has not been deemed completely satisfactory since certain cases are known where the results have differed appreciably from those obtained in the normal long time tests.

Mr. Cuthbertson has gone far to show that if this method is so modified that the load is steadily applied and is not increased suddenly, the results obtained are far more satisfactory, and as a practical test at any rate the method would appear to have very valuable applications.

University and Educational Intelligence

CAMBRIDGE.—Dr. G. Salt, research student of Gonville and Caius College, has been elected as first holder of the Stringer fellowship, tenable at King's College, which is open to graduate members and research students of the University whose study and research fall within the fields of chemistry, experimental physics, or the chemistry or physiology of plant or animal life. Dr. Salt is a B.Sc. of the University of Alberta, and Sc.D. of Harvard University. He was elected to a Royal Society Moseley Research Studentship in 1932.

"WHAT is General Science ?" An editorial on this question in the October number of the *Progress of Education* (Aryabhushan Press, Poona; monthly, 12 annas) criticises the course proposed by the Academic Council of the University of Bombay in view of the inclusion in the matriculation syllabus of general science in place of the four alternative groups, physics and chemistry, botany and zoology, physiology and hygiene, and domestic science. The proposed course consists of only the elementary study of physics and chemistry, botany and zoology and physiology and hygiene, and the article points out that whilst this is perhaps advantageous to those who will later specialise in science, it is ill-adapted to the professed object of the change in the syllabus, namely, to equip every student with that modicum of scientific knowledge which is indispensable for the intelligent appreciation of his material environment, a knowledge as necessary to-day as that of language, history, or arithmetic. The scope of modern science and its applications is so vast that there cannot be at the matriculation stage the same general science for students with all sorts of environments and there should be, it is suggested, a choice of several courses which would include (*a*) for students in big cities—mainly physics and chemistry; (*b*) for those in rural areas—mainly agriculture and allied topics; (*c*) for industrial areas—practical arts like weaving, wood or iron work, machine repairs, printing, moulding; (*d*) for girls—domestic science; (*e*) for all—science of health. After matriculation, the student should supplement this course until he has acquired such further knowledge of science as he will need, not as a specialist in science but as a man of culture.

THE problem of improving examination methods has received much more attention in the United States than in Great Britain, and the Carnegie Corporation has spent large amounts in recent years in devising objective tests in modern languages. It has now taken steps to further investigations in Great Britain, and, as a result of a private international conference held in 1931 at Eastbourne, under the auspices of the Carnegie Corporation, the Carnegie Foundation, and the International Institute of Teachers College, Columbia University, five independent committees have been set up, and promised a grant for three years, in England, Scotland, France, Germany, and Switzerland, to investigate such problems connected with examination systems of the countries concerned as they deem desirable. The English "International Institute Examinations Enquiry" Committee is constituted as follows :—Sir Michael Sadler (chairman), Dr. P. B. Ballard, Dr. C. Delisle Burns, Prof. Cyril Burt, Sir Philip Hartog (director), Sir Percy Nunn, Prof. C. Spearman, and Prof. Godfrey H. Thomson (replacing the late Prof. Graham Wallas, who was an original member of the Committee). The Scottish Committee, which is a committee of the Scottish Council for Research in Education, is constituted as follows :—Prof. Godfrey H. Thomson (convener), Dr. William Boyd, Prof. James Drever, Mr. Thomas Henderson (honorary secretary), Mr. W. A. F. Hepburn, Dr. J. Mackie, Prof. W. W. McClelland, Dr. Robert Rusk, and Dr. J. C. Smith. The chairman of the French Committee is M. Desclos, Sous-Directeur, Office National des Universités et des Ecoles Françaises, Paris; the chairman of the German Committee is Prof. C. H. Becker, formerly Prussian Minister for Education, and the chairman of the Swiss Committee is Prof. A. Malche, professor of pedagogy in the University of Geneva.

Calendar of Nature Topics

February Fill-dyke

In western Europe, February is proverbially associated with flowing streams and a damp countryside. In the French Revolutionary Calendar of 1793, the period January 20–February 18 was the month 'Pluviôse' or 'rainy', but even allowing for its shortness, February is no rainier than January or March. The name 'Fill-dyke' may have originated from the melting of the January snows, but during the present century deep snow has been rare. The title is still justified, however, for in winter evaporation is negligible and the rains of December and January replenish the underground reservoirs and leave the soil in a water-logged condition. Thus the streams are often at their highest in February and fall rapidly under the drying conditions of March.

Tilling the Soil

Writing in 1661, Mathew Stevenson in "The Twelve Moneths" says of February : "Now methinks I see the Husbandman dresse afresh his rusty plowshare to teare up the stiffer clay grounds . . ." Although mechanical science has greatly improved the structure and design of cultivating implements, until quite recently all the major cultivations, whether by horse or tractor, were on the age-old principles of the turning action of the plough or the shattering effect of the hoe. A new system is now being introduced and scientifically examined. Rotary tillage, the milling of the soil by revolving tines, instead of the bodily movement or disturbance by the drawn implement, is the most natural way in which the internal combustion engine can be directed to the comminution of the soil. Rotary cultivation is gaining ground in small occupations, where it is employed as a substitute for the joint action of spade and rake; but larger machines are being developed for full-scale cultivation, where they will do in one operation the work of tractor plough and the cultivators and harrows which follow them. The aim of all cultivation should be, so far as possible, to let the weather do the work. Alternate wetting and drying, frost and thaw, have a wonderful mellowing effect on soil, and this greatly assists the formation of a seed-bed whether by the older or newer implements. To force a tilth against the weather is an expensive operation and at best only a makeshift; but in case of need the rotary cultivator presents more opportunities in this direction than the traditional implement.

February 1. Partridge Shooting Ends

The close of the partridge shooting season is adjusted to avoid disturbance of the new season's crop of partridges, for during February the birds begin to pair. Indeed, pairing sometimes begins in January and may be delayed until March, but a mean date about mid-February justifies the end of the legal open season. The courtship period is prolonged, for eggs are scarcely to be expected until the beginning of May, and although there is an absence of the elaborate plumage displays in which many game-birds indulge, the excitement of the occasion is expressed in challenges between cocks and continual 'scrapping'.

Frost and Shore Animals

In February 1855, when Robert Chambers was in the chair, Hugh Miller described to the fellows of the Royal Physical Society of Edinburgh his experience of the result of "the late severe frost" upon the shore animals of the Firth of Forth. "The present intense frost, coincident at new moon with a stream tide, has killed many of the littoral shell-fish around our shores, and they now lie by thousands and tens of thousands along the beach. On the beach below Portobello, and for at least a mile on the western side of the town, they are chiefly of two species—*Solen siliqua*, or the edible spout-fish or razor-fish, and *Mactra stultorum*, or the fool's cockle, both of them molluscs which burrow in the sands above the low water mark of stream tides. The spout-fishes when first thrown ashore were carried away by pail and basketfuls by the poorer people, and yet of their shells enough remain, in the space of half a mile, to load several carts; but the fishes themselves, devoured by myriads of birds, chiefly gulls, have already disappeared. The Mactra, though they may be picked up in some places by basketfuls, are less abundant. . . . Their wholesale destruction by a frost, a few degrees more intense than is common in our climate, strikingly shows how simply, by slight changes of climate induced by physical causes, whole races of animals may become extinct. It exemplifies, too, how destruction may fall upon insulated species, while from some peculiarity of habitat, or hardiness of constitution, their conquerors escape. There are two species of Solen in the Firth, *S. siliqua* and *S. ensis*; but we have not seen, on the present occasion, a single dead individual of the latter species; and of at least four species of Mactra, *Mactra stultorum* seems alone to have suffered." Later on, Hugh Miller found, in addition to these two species which at first were almost exclusively cast up, considerable numbers of smaller molluscs, amongst which *Solen ensis* was represented. Of the smaller forms *Tellina fabula* suffered most.

Frost as an agent of death was apparently selective; but absence of knowledge about the relative numbers of different species living on the shore in question, made speculation hazardous. Hugh Miller was satisfied, however, that "none of the molluscs killed in any considerable abundance by the present intense frost seem to be truly arboreal species".

Selective Mortality in Shore Waters due to Frost

A recent example, in which successive annual populations have been compared, supplies the data which Miller lacked. The early months of 1929 brought a spell of exceedingly cold weather which was duly recorded in the temperature readings taken in the sea at the oyster beds of Blackwater Estuary. The average temperature is lowest in mid-January, when for the years 1926–28 it reached slightly under 4° C. The seashore differs from the open sea in that its water temperature shows little of the lag which throws the minimum temperature of the ocean back into March, because of the readiness with which shallow waters cool and of the inflow in estuaries of chilled fresh water from the land. Therefore exceptionally cold air temperatures were reflected over the oyster beds, so that in February 1929 a minimum water temperature of less than $-1°$ C. was recorded. (See J. H. Orton and H. M. Lewis in *J. Mar. Biol. Ass.*, 17, 301–313; 1932: and J. H. Orton in *Acta Phænologica*, 1, 129–132; 1932.)

The result was selective destruction of the molluscs associated with the oyster beds. In 1928 the relative percentages, amongst 1,730 individuals, of three well-known species were: *Urosalpinx cinerea* 7·8 per cent, *Murex* (*Ocinebra*) *erinacea* 41·2 per cent, *Purpura* (*Nucella*) *lapillus* 51 per cent. After the great frost in 1929, the relative percentages were respectively:—1929—83·4, 0 1, and 16·6, in a total of 1,184 individuals; and in 1930—84·5, 0·1, and 15·4, in a total of 7,927 individuals. There can be little doubt that the mortality traceable in the *Murex* figures was due to the unusual conditions. Further, it was noted that on the Whitstable oyster beds, where the sea-urchin *Psammechinus miliaris* was abundant in the years 1920–28, so that Prof. Orton could obtain samples of five hundred individuals without difficulty, after the opening months of 1929 the species entirely disappeared on the shallower inshore grounds, where the hydrographical conditions are similar to those over the Blackwater beds. But in small numbers the sea-urchin could still be obtained in the deeper off-shore waters.

Societies and Academies

LONDON

Royal Society, Jan. 19. C. N. HINSHELWOOD, E. A. MOELWYN-HUGHES and A. C. ROLFE: The combination of hydrogen and oxygen in a silver vessel. The reaction shows the characteristics of a surface reaction up to 700°. There is no sign of the development of reaction chains in the gas. The inhibition of the gas reaction is attributed to the catalytic destruction at the silver–silver oxide surface of the active species which would normally propagate the chains. R. L. Smith-Rose: The electrical properties of soil for alternating currents; with particular reference to radio-frequencies. The first part of this paper comprises a summary of previous investigations of the conductivity and dielectric constant of soil at various frequencies from 50 cycles per second up to 200 million cycles per second. The second part of the paper describes the application of a laboratory method for measuring these constants on samples of soil taken from selected sites at the National Physical Laboratory, Teddington. The conductivity varies from less than 10^6 E.S.U. for dry soil, up to a value of approximately 10^8 E.S.U. for normal moisture content. Corresponding values for the dielectric constant range from 2 or 3 for dry soil up to about 20 for moist soil at high radio frequencies. Measurements on a number of samples of soil taken at random from several other sites are included, and show that both the normal moisture content and the conductivity can have values which are appreciably higher than those experienced at Teddington. The paper concludes with a brief discussion of the penetration of radio-frequency currents in the earth, and the effective depth of penetration has been calculated in some instances. C. B. O. Mohr and F. H. Nicoll: (1) Inelastic electron scattering in gases. The angular distribution of inelastically scattered electrons has been investigated in helium, argon and mercury vapour for the angular range between 20° and 160°. The scattered electrons of different energies were sorted out by a uniform radial electrostatic field. The results suggest that the problem of the scattering of electrons by atoms is not so serious as might be expected from a consideration of the various complicating processes which are involved, and that in the explanation of the observed results for the elastic and inelastic scattering of electrons by the heavier atoms, it is merely the 'size' of the atom which is of fundamental importance. (2) The large angle scattering of electrons in gases (2). With an apparatus described in a previous paper the angular distributions of scattered electrons have been measured to 160° for 30-150-volt electrons. The elastic scattering has been investigated in hydrogen, carbon dioxide, nitrogen, neon, methane, hydrogen sulphide, and phosphine, while the inelastic scattering has also been measured in the first four gases. The diffraction maxima and minima which appear in the inelastic angular distributions are closely similar to those obtained for the elastic scattering. The curves for the elastic scattering show a gradual change in form for successive elements in the periodic table. The general shape of the experimental curves for the elastic and inelastic scattering is qualitatively accounted for, with the aid of a simple picture involving merely the 'size' of the atom.

Paris

Academy of Sciences, Dec. 5 (195, 1049–1112; 1932). L. Cayeux: The modes of existence of glauconite in limestone. A discussion of the relation between the presence of glauconite and Foraminifera in limestone. Edm. Sergent, A. Donatien, L. Parrot and F. Lestoquard. The experimental suppression of sexual reproduction in *Theileria dispar*. In this organism, which by the artificial means of blood transfusion is perpetuated by schizogonic multiplication, the sexuality disappears. As a practical consequence, a benign virus of theileriosis can be used as a vaccine without creating carriers of dangerous germs. Bertrand Gambier: The intersection of two plane algebraical curves. Jacques Devisme: A quasi-Euclidian space of three dimensions connected with P. Humbert's equation. Maurice Gevrey: Complements to a preceding note on systems of the parabolic type: problems with non-linear limits. Ed. and G. Guillaume: The definition of the unit of value. René Lucas: The diffraction of light by elastic waves. G. A. Beauvais: The total reflection of Hertzian waves. Experimental study of the reflection of Hertzian waves (18 cm. wave-length) by a paraffin wax prism. Max Morand and A. Hautot. The fine structure of the carbon line K_α. The line is complex and contains at least two components: the approximate distance of the two components is 0·6 A. Adrien Karl: The analysis of primary radioactive minerals. The method is based on the treatment at 500°–550°C. with carbonyl chloride, thus removing metals forming volatile chlorides. Jean Galibourg: Certain singularities of the extension curves of steels at high temperatures. P. Vallet: Study of the decomposition of some complex platinum compounds at progressively increasing temperatures. Experiments on the reduction of chlorplatinic acid and its salts, with the view of preparing finely divided platinum at the lowest possible temperature. A. Perret and A. M. Krawczynski. The action of some organo-mercury compounds on solutions of hexamethylene-tetramine. R. Sutra: The acetolysis of starch. P. Carré and D. Libermann. The mechanism of the reaction of phosphorus pentachloride on neutral alkyl sulphites. The primary reaction gives phosphoryl chloride, alkyl chloride and the chloride AOSOCl, where A is the alkyl group. Four secondary reactions may occur, depending on the temperature. Ch. Prévost. A colouring matter derived from tripropynylcarbinol. Hubert Cerf: Researches on the nitro-amines. Aurélio Cocco: A new method of amination of organic compounds. Paul Gaubert. The rotation of crystals floating on the surface of liquids. H. Lagotala and Ch. Couchet. The tectonic on the French Congo. Louis Mengaud: The structure of the Cantabrian chain. P. Russo: The tectonic significance of the folds with reference to the Eocene to the east of Kasbah Tadla (Central Morocco). Albert de Lapparent: The neighbourhood of Bauduen (Var). Francis Ruellan: A bank of shingle and a fossil sea floor in the cliffs of Trez-Bihan at Telgruc (Finistère). G. Grenet: The geothermic gradient in Limagne. Advantage was taken of a 200 metre boring to measure the temperatures at a depth of 192 metres and at the ground level. The results were in good agreement with the earlier observations of Macholles, confirming the view that the geothermic gradient is of the order of 14 metres over the greater part of the Limagne. A. Savornin: Some measurements of magnetic anomalies at Madagascar. Data are given for 23 stations: the observations were made in May and June, 1932. L. J. and F. Mercier: A new method of preparing marrubiine. A simplification of Gordin's method of extraction from the plant, yielding a crystalline product melting at 3° C. higher than Gordin's product. Em. Miège: The anabiosis and revitalisation of wheat embryos. Alexandre Lipschütz: New researches on the transplantation of ovaries preserved outside the organism. An ovary, isolated and kept at 12°-18° C. for eleven days, has survived as an intrarenal graft for two years: another dried before transplantation, after losing about 40 per cent of its weight, has survived as an intrarenal graft for 30 months. P. Chevey: The nature of the influence exercised by the inundated forest of the Grand Lac of Cambogia on the velocity of growth of fishes. Mlle. Yvonne Garreau: The oxidation products of levulose by ammoniacal copper carbonate and atmospheric oxygen, in dilute solution, pH = 7, and at the ordinary temperature. Oxalic acid and oxymethyl-4-imidazol were identified among the oxidation products. A. Rochaix, P. Sédallian and Mme. Clavel: Inhibiting properties towards *A* paratyphic, shown in paratyphic cultures.

Geneva

Society of Physics and Natural History, Nov. 3. G. Tiercy and P. Berger: Note on aerological soundings and the wind gradient in Switzerland. Pilot balloons give very uncertain results. The theoretical equation for the vertical movement of pilot balloons shows that the upward velocity of the balloon is continually varying, starting from the ground. The velocity of the wind theoretically calculated and based on good observations in the mountains corresponds better with the true wind velocity. G. GUTZEIT and R. MONNIER: The utilisation of some azo derivatives of oxyquinoline as reagents in qualitative analysis. In a preliminary study, the authors describe the spot colour reactions of the cations of the heavy metals with several azo derivatives of oxyquinoline. The presence of a sulpho group in the substituted molecule makes the colour reactions more clear. H. LAGOTALA: The stratigraphical study of the Mindouli-Mines region. The author makes clear the stratigraphical complexity of this part of the French Congo, due to numerous faults leading to repetition of facies. J. WEIGLE: Dispersion in the Hertzian domain. Experiments show indubitably that polarised molecules dissolved in a viscous medium associate in part to form large groups in the solvent. Certain X-ray measurements had suggested this arrangement, but the full proof had been lacking up to the present.

Forthcoming Events

Monday, Jan. 30

ROYAL GEOGRAPHICAL SOCIETY, at 5.30.—(Geographical Film).—Lieut.-Commander J. L. F. Hunt: "The Sahara and the Ivory Coast".

Wednesday, Feb. 1

UNIVERSITY COLLEGE, LONDON, at 5.30.—K. Ryde: "The Reference Library of a Modern Town and What it Can do for You".

Thursday, Feb. 2

UNIVERSITY COLLEGE, LONDON, at 5.30.—(Newmarch Lectures in Statistics).—Dr. L. J. Comrie: "Modern Methods of Calculation" (succeeding lectures on Feb. 9, 16, 23, March 2 and 9).

Petroleum Technology and Chemical Industry

If we survey the course of evolution of petroleum technology, particularly as it concerns the treatment, refining and utilisation of crude oil and its products, it is an impressive fact that despite a magnitude of growth and ramifications of the industry it supports in modern life, equally an obvious dependence throughout on the functions of certain applied major sciences, it has long maintained, outwardly at all events, a remarkable measure of autonomy. No one ever seriously suggested, because chemistry and physics, for example, enter largely into the technique of manufacture of innumerable products from the raw material, that this technology is *ipso facto* an offspring of co-ordinated influences of these or any other sciences. On the contrary, oil technology has grown in an almost unique fashion. It has been urged by an overwhelming but universal impulse. It has rapidly strengthened from an innate knowledge of its inherent power as a world force, casually absorbing, but diligently applying, just those established principles of appropriate natural science as would meet its needs. It has known few of the struggles of just as important, but none the less subservient, industrial technologies.

No one science nor the more mundane interests of international, economic and political life, which petroleum has profoundly influenced in latter years, can legitimately claim any fundamental control over the technology even now. There are signs, however, that this order of things is destined to change, if indeed the change is not now actually taking place.

In a welter of conflicting difficulties through which the industry has been and still is passing, certain facts stand out as pre-eminent in any consideration of the situation. Over-production, not only of crude oil but also of many of its products; waste; curtailed consumption; increasing competition with commodities serving similar purposes but derived from different raw materials; vicissitudes of current international commerce; all these combine to create within the industry an acute self-consciousness of stifled activity, probably for the first time in its history. The repercussions of this have not been without their corresponding reaction on the technology. No one can really see far ahead with precision. Even the convictions of those who profess to know carry little more than temporary weight, since they seem to lack firm and definite foundation in a much disturbed ground.

Into this bewildering maze of circumstances there has been flung, with considerable force recently, the challenge of synthetic oil from hydrogenation process. What is the significance of this incursion? It is inconceivable, aside from all economic argument, that this factor in the situation can be other than one to be seriously reckoned with; it is disturbing even now; it is bound to be formidable ultimately in the petroleum industry, and to have far-reaching consequences on the technical operations involved therein.

The history of chemical industry is rich in examples of new processes in which the established commercial success was achieved among the ruins of discarded doubts and scepticisms at the outset. Hydrogenation is a long-tried process; it has, as a technical procedure, been brought to a high state of efficiency. It is chemical engineering at its best. Oil production from coal, whether by this or by any other means is, and must inevitably be, on whatever scale achieved, a product of chemical industry. To this extent, the product differs fundamentally from anything realised by the petroleum industry.

The coal industry *per se* is non-existent in the same sense in which we contemplate and assess the activities of the oil industry to-day. It discarded individuality long ago in favour of second-hand recognition through the medium of dependent products such as gas, coal-tar, dyes and allied substances, the enormous developments of which not only built up relevant commercial activities, but also have contributed more to the growth of chemical industry as a whole than probably any other branch of it. Hydrogenated coal-oil when it arrives as an accepted economic commodity will simply add another weapon to the already powerful array of forces which chemistry commands in the sway of modern civilisation.

The moral to the petroleum industry in general, and to the technology in particular, is surely obvious. There has for long been the broadest possible overlap between research within the petroleum and chemical industries, at least as technically interpreted, and where basic substances common to both have been involved. Research, temporarily retarded as it may have been by prevalent conditions, has none the less forged ahead in chemical industry, as keenly animated as ever by the desire to conquer fresh fields and produce new outlets for natural resources at the present time only partially or extravagantly exploited. The trend of petroleum technology, if it is to compete with the incidence of an independent and biased chemical industry, must, apart from the actual winning of oil, inevitably lead in the direction of finding new and extended uses for its raw material and basic products.

It is insufficient to point to a succession of highly refined products of crude oil such as petroleum, paraffin, lubricating and fuel oils, wax and asphaltic bitumen—the high standard of production of which to-day is freely acknowledged —as though these represent monuments to final achievement. There can be no such finality, and research must aim far beyond the mere improvement of technique of production, the multiplicity of types and qualities of distillates, and the goal of supplying markets with what they have been accustomed.

In point of fact, the domain of petroleum technology is no longer inviolable; and if it does not of its own initiative expand actively into the realm of chemical industry, then assuredly will the latter gradually stretch the tide-mark of overlap until the merger is complete.

Petroleum, like coal, is a wasting asset. It is no longer the prerogative of the oil industry alone and, as a natural resource still possessing immense latent possibilities of more efficient development, it must come into line with other basic raw materials and be subject to that vigorous independent investigation which is afforded by intensive chemical research. Only in this way will it avoid some of the calamitous happenings which have led to the acute problems of efficient coal exploitation and utilisation, for which, it is to be noted, chemical industry has gone a long way to find a practical and economic solution. H. B. M.

Age of Retirement in India

UNDER the title "The Fifty-five Year Rule", the November issue of the Indian monthly, *Current Science*, contains a long leading article advocating the abolition of retirement from educational posts at the age of fifty-five, as is now compulsory under the fundamental rules, and the raising of the age limit to sixty years in the first instance, or making such appointments for life. We have read the article with some surprise, since we are convinced that the concensus of opinion of those engaged in educational work in Great Britain regards the comparatively recent introduction of the Universities' Superannuation Scheme with its corollary, a compulsory age of retirement, as a distinct contribution both to the efficiency of the universities and of the schools.

Although it is not uncommon for men of mature age to make valuable direct contributions to knowledge, there is no doubt that with increasing years their teaching, whether it be in the school class room or the university lecture theatre, tends to become stereotyped and lacking in inspiration. Furthermore, they show less and less inclination to initiate young students into the methods of research, although they themselves may continue to be actively engaged therein. A not unimportant feature of the superannuation scheme has been to accelerate the promotion of the younger men and so stimulate employment. So far as we can gather, the main objection to compulsory retirement is that it deprives the university of the services of men of mature experience, but we doubt if this is actually so in practice. It is now almost invariably the custom to confer upon the retiring professor the title of emeritus, which is recognised as carrying with it the right to laboratory accommodation in his old department, a privilege of which advantage is frequently taken.

The writer of the article in *Current Science* appears to be under the impression that professorships in European universities are life appointments. As a matter of fact, there remain a few professorships in Scottish Universities and at Oxford and Cambridge where a definite age of retirement has not been assigned, but as these fall vacant the general practice of retirement at sixty is being adopted. It is true that the German universities do not fix a date for retirement, but in that country a professor's pension is the same as his salary, and consequently there is not the same temptation as there is in Great Britain and in India to continue in office after effective service can be rendered.

It is suggested in the article that, as the result of the great advances made in preventive medicine, retirement at the early age of fifty-five is no longer necessary in India. Whilst the increased security of life in the East might be used as an argument for raising the retiring age to sixty, we doubt whether this is actually the case. Climate cannot be altered. The Indian matures much earlier than the European and he ages correspondingly earlier, so that as a general rule the present retiring age seems to be comparable to that prescribed in England.

It is pointed out in the article that though the Government has decided to terminate the services of professors and others in the educational service at fifty-five years of age, this is not the practice in the judiciary or administrative posts of cabinet rank. Though this suggests unjust inequality of treatment, we think the conditions are different in the two groups. One of the main essentials for success in education is originality, a gift more common in youth than in age; this qualification is scarcely required on the Bench. In the field of higher administration we note a growing tendency to find room for the younger men, and we think this is likely to increase in the future.

While we agree with the view expressed in the article that a man is not necessarily disqualified physically or mentally for further useful service in India when he reaches the age of fifty-five, we believe it is not usually desirable for Europeans to remain at work in that country beyond that age. If, however, a university finds it to the advantage of a department to retain a teacher after the age of fifty-five, a man who is still active at that age ought to be able to expect to have his period of service extended to the age of sixty. It is the practice in some educational institutions to make these extensions by one year at a time, and we suggest that if the universities could extend the services by such a period, not exceeding five years in all, after considering the merits of each case, there could be little cause of complaint.

Evolution and Mechanism of Hearing

Hearing in Man and Animals. By R. T. Beatty. Pp. xi+227. (London: G. Bell and Sons, Ltd., 1932.) 12*s*. net.

THE study of the evolution of the sense-organs has a fascination for the general reader as well as the scientific worker. Our knowledge of the world around us is dependent on the reaction between various forms of physical energy and the appropriate sense organs. Some of the latter, such as touch, smell, taste and sight, are common to all vertebrates and are found in much lower forms of life, but hearing is relatively uncommon and may be regarded as a 'recent' development. In many of the lower forms of life, for example, in insects and fishes, the sense of hearing is either entirely absent or exists in a most rudimentary form.

For its proper understanding, audition requires a knowledge of anatomy, physiology, physics and psychology. Specialists working in one or other of these sciences clearly have difficulty in following developments in the others. This tendency has resulted in the accumulation of a large mass of detailed and highly specialised information which is not easily accessible or intelligible to workers in a different scientific branch of the subject. The need has long been felt that such information should be collected and correlated.

The first important step to this end was made by the Physical Society in its published discussions on "Audition" and "Vision". In these publications the work of physiologists, physicists and psychologists is collected under the same cover. But this is not sufficient. A further important step is still required, namely, to present the collected data in the form of a connected whole, written in a language which all can understand. This work has been carried out in a remarkably efficient manner by Dr. R. T. Beatty in the work under notice. Here one may read for the first time, in clearly expressed terms, a coherent description of fascinating researches in widely different fields of science.

In the preface, the purpose of the book is stated "to convey in plain terms to the general reader a connected account of the phenomena of audition in living creatures, and of the various mechanisms by which animals are made sensitive to the range of sounds which is important for their welfare". Dr. Beatty has fulfilled his purpose in a very satisfactory manner. The literary style is delightful and the information contained in the book will be satisfying and instructive not only to the general reader, to whom it is primarily addressed, but also to a wide range of scientific workers, teachers and research workers. The two-page list of acknowledgments at the beginning of the book is in itself interesting, indicating as it does the wide field over which the author has collected his material. This is further supported by the comprehensive list of references at the end of each chapter of the book.

The opening chapter gives a detailed description of the human ear and the functions of the various parts. The function of the chain of ossicles in the middle ear is particularly interesting as it involves a principle frequently occurring in technical acoustics. The flexible diaphragm, the ear drum, receives sound energy from the surrounding air and transmits it to the liquid-filled cochlea. The efficient transmission of this energy from a relatively light and yielding medium to a heavy, resistant fluid, requires the intermediary of a mechanical transformer, a lever, having the correct lever ratio. This is provided by the chain of bones.

One of the most fascinating chapters of the book is that which describes the evolution of the ear. Commencing with the primitive auditory mechanisms in fishes, evolutionary growth is traced through amphibians, reptiles and birds, to mammals. A later chapter of equal interest deals particularly with hearing in animals. These chapters abound with new and interesting information. For example, the ears of insects are never found on the head. The external ear, which takes the form of a stretched membrane covering an opening in the exterior shell of the insect, may be placed in some cases on the thorax, or the abdomen, or, as in grasshoppers and crickets, just below the knee-joint of the forelegs. Cases are recorded in which the external hairs of insects play a part in the reception of sound, and certain types of caterpillar respond to the human voice by suddenly raising the front part of the body.

Dr. Beatty explodes a few time-honoured beliefs. Fishermen should note, in spite of Isaac Walton's statements to the contrary, that fish cannot hear air-borne sounds. The angler is at last released from bondage and he may now converse freely whilst plying his rod. The sounds produced by his boots, knocking against the hull of the boat or tramping on the river bank, are on the contrary conveyed readily to the fish's auditory apparatus with disastrous results to the catch! It is a little disappointing to learn that snakes are deaf to air-borne sounds and that the piping of the snake charmer charms only the audience. Dogs, on the other hand, are extremely sensitive to sounds. Pavlov's experiments indicate that they have a sense of absolute pitch which considerably surpasses that of human beings. Furthermore, their frequency range of audibility is much greater, extending from very low sub-audible (that is, to human ears) to supersonic frequencies. Experiments reveal also that they can readily discriminate between the pitch of two tones only a quarter of a semi-tone apart. Such remarkable observations on the dog's auditory apparatus have led to the suggestion that hearing in man is on the downward grade, not due to imperfection in the ear, but from defect of nerve connexions in the brain. "We must remember that man stands alone in the animal kingdom in his power to interpret speech, and that large cortical areas have been given over for that purpose, no doubt at the expense of the perception of subtle variations in pitch and rhythm which is so clearly manifest in the case of the dog".

A short but interesting chapter deals with the happenings in the human brain when the nerve endings in the cochlea are stimulated by an external sound. The nerve impulse is relayed from one station to another until it reaches the 'conscious' part of the brain. These relay stations not only pass on information to the brain but also inform other nerve centres which control the automatic reflex movements of the eye and other parts of the body. At its maximum sensitiveness, the ear can respond to a sound intensity of 10^{-9} microwatt per square centimetre, a quantity of the same magnitude as light from a candle at a distance of eight miles, assuming perfectly transparent air. The ear is a more efficient receptor than the eye.

Two chapters are devoted to the study of theories of hearing. Although the resonance theory holds the field, there are still many discrepancies in detail which require further investigation. Interesting experiments on animals are described in which degeneration of certain parts of the organ of Corti over a limited region is produced by a long-continued tone. Pavlov's experiments on dogs and Held's work on guinea pigs show that surgical operations in which a small portion of the cochlea is destroyed, result in localised deafness the frequency range of which depends on the point of operation.

The book concludes with three interesting chapters on music, noise and defects of hearing. The chapter on music, dealing as it does with origins, in respect of style and subject matter, would form a fitting chapter in Wells's "Outline of History". The treatment of noise is essentially modern, bringing the reader into touch with the special problems of civilisation, with its roar of machinery and traffic. The effects of noise on working power and on the nervous system are examined critically, and an estimate is made of the 'cost' of noise. The final chapter on defects of hearing appropriately follows the chapter on noise.

Dr. Beatty deserves unqualified congratulation on his success in producing this excellent book on hearing. It is well written, well illustrated and well reproduced. Readers will look forward to a companion volume on "Sight in Man and Animals".

The Spiders of Denmark

The Biology of Spiders: with Especial Reference to the Danish Fauna. By E. Nielsen. Vol. 1. Pp. 248 + 32 plates. Vol. 2. Pp. 724 + 5 plates. (Copenhagen: Levin and Munksgaard; London: Williams and Norgate, Ltd., 1932.) 30*s*.

THIS substantial work is a record of observations of the habits of Danish spiders, and appears in a somewhat unusual form. The full accounts are contained in the second volume, written in Danish and fully illustrated; the first volume is a slightly condensed translation, almost without illustrations save for a collection of plates at the end. Thus the first volume forms an English guide to the second. The Danish preface is dated May 1, 1928, and the English preface September 1, 1931, so that the first volume includes some recent observations not contained in the second. On the other hand, the very complete Danish account of the structure of spiders is omitted from the English volume.

Part I of this work is a general account of the life history of spiders; Part II records the author's observations on the individual species, arranged according to Simon's classification. It is unfortunate that the book was written just too soon to adopt the system contained in Prof. Petrunkevitch's "Systema Aranearum", as it may lead to a tendency to perpetuate Simon's now obsolescent method.

The observations consist chiefly in descriptions of the webs, the cocoons, and the feeding and mating habits. It would not be possible to study spiders as long and as carefully as Mr. Nielsen has done without breaking new ground, and there is much that is new in this work. The most striking is undoubtedly the careful account of the separate functions of the claws and tufts of 'hair' on a spider's foot as it grasps a silk thread or runs over a web. The author describes how the set of the claws gives a twist to the thread, and how the hair-tuft forms a springy pad which detaches the claw as the spider runs—a very careful analysis of a process which is unexpectedly elaborate. A large section of the work, Part III, deals with the parasites of spiders. Mr. Nielsen writes of these with the authority of a specialist, and this account of his work is extremely welcome. Other features which will be of interest to English readers are his descriptions of the triangle-spider, *Hyptiotes*, and the water-spider, *Argyroneta*, of the burrowing wolf-spiders, and of the temporary egg-teeth on the palpi of *Zilla*, which help the young to burst the egg-membrane.

The author is a skilled photographer and the work contains more than four hundred reproductions of his work of quite outstanding merit. Photographs of spiders are never easy to obtain and there is no other book known to us in which the photographs approach the excellence of those used to illustrate these volumes.

Mr. Nielsen is content to describe what he has seen, and his book would more accurately be described as a natural history than a biology. There is very little discussion of the general significance or broader aspects of the facts observed, save for some careful analyses of various cocoons. Indeed a blemish on the work is the naive way in which the author endows spiders with mental attributes. He describes a female *Agelena* as "very affectionate", and says that young wolf-spiders can cling to their mother's back, "being from birth acquainted with the laws of inertia".

The second volume ends with a list of Danish spiders, and a supplement to this in the first volume brings the total to 372 species. About four-fifths of these are also British. This is a valuable addition to the book, and makes Denmark more fortunate than England, for no list of British spiders has appeared for more than thirty years. Both the author and his publishers may thus be congratulated on the production of a most acceptable book. T. H. S.

Diphtheria

Diphtheria, Past and Present: its Ætiology, Distribution, Transmission and Prevention. By Dr. J. Graham Forbes. Pp. xx + 832. (London: John Bale, Sons, and Danielsson, Ltd., 1932.) 45*s*. net.

DIPHTHERIA is one of the best understood human bacterial diseases and its study has enriched bacteriology with several ideas of prime importance. The isolation of the bacillus by Loeffler (1884) provided a means of precise diagnosis: the discovery of antitoxin by Behring (1890) opened up an entirely new field in prevention and therapy. Theobald Smith (1907) saw the possibility of making people immune by the inoculation of toxin: Schick (1908) made this practicable by devising his simple test for individual immunity. Diphtheria is also the disease in which it was first shown that the lesions could be produced by toxin without the bacilli and in which the possibility of becoming immune by subinfection without any actual illness was first clearly recognised.

Pathologist, bacteriologist and hygienist therefore all know a great deal about the diphtheria bacillus and what it does, which is set out in the monograph published by the Medical Research Council in 1923. Since almost anyone can be deliberately immunised (nowadays with toxoid-antitoxin mixtures) and scarcely any patients will die if they are given antitoxin at the outset, it seems that the disease might well be abolished altogether if practical hygiene and medicine were a sufficiently accurate reflection of bacteriological knowledge. In fact, children still catch diphtheria and a proportion of them still die of it, and Dr. Forbes's book consists of a very detailed account of the occurrence of the disease, what has been done in the way of prevention and what we may hope to achieve in the future. It seems clear from his account that the failure to get rid of diphtheria is due almost entirely to difficulties in practical application rather than to imperfections in knowledge.

The book is a voluminous expansion of the Milroy Lectures of 1929 and consists almost wholly of facts and figures; we could wish that Dr. Forbes had not been so sparing of commentary. It is, however, cheering to find that the intensive campaign of immunisation started by Park in New York in 1913 is at last having an effect on the diphtheria death-rate sufficient to satisfy the statisticians—"unfeeling men" as the late Sir Frederick Andrewes calls them in his preface.

Surface Catalysis

Von Davy und Döbereiner bis Deacon: ein halbes Jahrhundert Grenzflächenkatalyse. Von A. Mittasch und E. Theis. Pp. 278 + 16 Tafeln. (Berlin: Verlag Chemie G.m.b.H., 1932.) 18.50 gold marks.

DRS. MITTASCH AND THEIS have provided a charming record of work on surface catalysis during a period of half a century from Davy and Döbereiner to Deacon, and have dedicated it to Wilhelm Ostwald. The book is illustrated by portraits of the three workers whose names appear in the title and of twelve of their contemporaries, together with a more recent portrait of Prof. Horstmann, who died at Heidelberg in 1929. The narrative is also illustrated with some fourteen diagrams, including a series of Döbereiner lamps and allied devices for ignition with the help of spongy platinum or the like.

The scope of the work has been restricted by excluding the modern developments which have brought surface catalysis to the forefront as an industrial method of first-rate importance, and by omitting the important subject of homogeneous catalysis. The latter is referred to briefly in a "Review of Related and Separated Fields" (Chap. xiv) as well as in the final "Retrospect and Prospect" (Chap. xv). In this final chapter it is pointed out that a lull in the study of heterogeneous catalysis between 1875 and 1890 was followed by an intensive study of homogeneous catalysis; this preceded the great modern applications of surface catalysis, the foundations of which form the subject of the present monograph.

One of the earliest of these foundations was Davy's 'night lamp' (1818); in this lamp a platinum spiral was maintained in incandescence over the wick of a spirit lamp, of which the flame had been blown out. Döbereiner's discovery of the oxidation of alcohol to acetic acid by platinum black followed in 1831; and the ignition of oxyhydrogen mixtures, leading to the development of the Döbereiner lamp, in 1832. The term 'catalysis' was introduced by Berzelius in 1835, and was followed by a controversy with Liebig as to the nature of 'catalytic force'.

The application of catalysis to the preparation of sulphuric acid by the 'contact process' can be traced back to an English patent taken out in 1831 by Phillips, who proposed to use platinum for this purpose, whilst Robb in 1853 introduced the use of 'peroxide of iron'. In the same way, the catalytic oxidation of ammonia to nitric acid can be traced back to the work of Kuhlmann, who discovered in 1838 that nitric acid was formed when air and ammonia were passed over platinum heated to about 300°.

The early period in the history of surface catalysis closes with the technical development of Deacon's process for making chlorine by the catalytic oxidation of hydrogen chloride. This method can be traced back to the work of W. Henry in 1826, but was only developed into a practical process about 1870. The technical conditions in this case were not too difficult, since there was no need for the drastic purification by which alone success was finally achieved in the contact process for sulphuric acid; and the high temperatures and pressures which are required for the synthesis of ammonia, and for many other processes of catalytic hydrogenation, were also not yet needed. There was therefore a natural sequence in the industrial development of surface catalysis, and the authors are to be congratulated on the success with which they have brought out the logical character of this important chapter of chemical history.

Short Reviews

Traité de pyrométrie optique. Par Prof. Gustave Ribaud. (Encyclopédie photométrique, Cinquième section, Mesures sur l'émission, Tome 4.) Pp. xvi + 485. (Paris: Editions de la *Revue d'Optique théorique et instrumentale,* 1931.) 95 francs.

It is a remarkable sign of the progress of theoretical and experimental knowledge in a single branch of physics that a volume of nearly 500 closely printed pages should be required to give an account of modern optical pyrometry. In an interesting preface, M. Charles Fabry points out that the production of high temperatures in industrial and laboratory operations outstripped for a long period the methods of measuring such temperatures. For example, the gas thermometer, theoretically the simplest form, failed because no reservoir could be found which would retain its shape and remain absolutely impervious to gas at extremely high temperatures. The problem of measuring these temperatures was only effectively solved when the use of a material thermometer was abandoned and attention was concentrated on the radiation emitted by the body the temperature of which was to be found.

All the methods based on the examination of the associated radiation may be included under the name optical pyrometry. These methods are based on the laws of radiation of a black body due to Stefan, Wien, and Planck—laws which are discussed by Prof. Ribaud in the earlier part of the volume. The most valuable method is that of the disappearing filament optical pyrometer. The importance of this instrument is illustrated by its use in determining the temperature of tungsten lamps for an intercomparison of the high temperature scales of the leading standardising laboratories. For any point of the entire range from about 1,400° to 2,700° K. the maximum difference found in such an intercomparison was only a few degrees (W. E. Forsythe). Prof. Ribaud's book should be in the hands of all those who are concerned with high temperature measurements. H. S. A.

Prout's Hypothesis. Papers by Dr. William Prout (1815–16), J. S. Stas (1860) and C. Marignac (1860). (Alembic Club Reprints, No. 20.) Pp. 58. (Edinburgh: Oliver and Boyd; London: Gurney and Jackson, 1932.) 2*s*. 6*d*. net.

SOON after the classification of the chemical elements by Lavoisier, and the decomposition of the alkalis by Davy, the latter, in 1812, suggested that the "undecompounded substances" may be composed of hydrogen "with another principle yet unknown in the separate form". If we identify this principle with the electron, we have in this speculation (not mentioned in the present Alembic Club Reprint) an anticipation of the modern theory of atomic structure as striking as the prediction of isotopes by Crookes in 1886, and of the packing effect by Marignac in 1860. The logical development of Davy's idea was found in the papers of Prout (1815–1816), which are reprinted in the present volume, suggesting that atomic weights are whole multiples of that of hydrogen, and that "we may almost consider the πρώτη ὕλη of the ancients to be realised in hydrogen".

Stas's criticism of Prout's hypothesis (1860), on the basis of exact atomic weight determinations, leading him to the conclusion that it is "nothing but an illusion, a pure hypothesis contradicted by experiment", follows. The thoughtful commentary on Stas's paper by Marignac (1860), in which it is suggested that "while preserving the fundamental principle of . . . the hypothesis of the unity of matter", we might "suppose that the cause which has determined certain groupings of the atoms of the sole primordial substance" may have exercised an influence such that "the weight of each group might not be exactly the sum of the weights of the primordial atoms composing it", was entirely disregarded.

The further progress of the matter is very ably summarised in a historical introduction to the booklet, which is one of great interest and fully maintains the high standard of the Alembic Club Reprints.

The Standard Natural History: from Amœba to Man. Contributors: G. J. Arrow, M. Burton, Dr. W. T. Calman, J. G. Dollman, Dr. F. W. Edwards, C. C. A. Monro, J. R. Norman, H. W. Parker, W. P. Pycraft, N. D. Riley, G. C. Robson, Theodore H. Savory. Edited by W. P. Pycraft. Pp. xiv + 942 + 12 plates. (London and New York: Frederick Warne and Co., Ltd., 1931.) 15*s*. net.

IT is somewhat of a venture to compress a knowledge of the animal kingdom, with its three-quarters of a million species, into a single volume, and preserve at the same time a balance between the different groups. But here the attempt has been successfully made, the more obscure groups receiving due place, the more familiar groups, such as birds and mammals, properly being singled out for relatively more expansive treatment.

The systematic cast of the book gives a false impression of its contents, for bare description has been reduced to a minimum and living interest has been sustained by the accounts of habits and of the links between structure and environment; the section on Diptera is a fine example of condensed biological survey. In most of the sections there is a freshness of treatment traceable to the specialised knowledge of the contributors and among the 900 odd illustrations we are grateful for a great many new figures, although several of the pictures of mammals and birds, from indifferent museum specimens, might have been bettered.

Bentham's Theory of Fictions. By C. K. Ogden. (International Library of Psychology, Philosophy and Scientific Method.) Pp. clii + 161 + 3 plates. (London: Kegan Paul and Co., Ltd., 1932.) 12*s*. 6*d*. net.

IN a public lecture recently given in London, Prof. Schlick, of Vienna, said that if philosophers had given more consideration to linguistics, the history of our civilisation would have been different. Indeed, it seems that only a realistic analysis of language could purify philosophy and the special sciences of much of their misleading verbiage. The modern schools of mathematical logicians have done useful work in this direction. Yet the developments of the present should not make us forget the attempts of the past. A thorough study of Bentham's "Theory of Fictions" will prove it to be a mine of information and suggestions. Mr. Ogden has done a real service to philosophy by publishing this book, which will be considered by many as a revelation and as a valuable basis for further research. The actual interest of Bentham's "Theory of Fictions" is enhanced by Mr. Ogden's very able introduction. T. G.

The Spirit of Language in Civilization. By Karl Vossler. Translated by Oscar Oeser. (International Library of Psychology, Philosophy and Scientific Method.) Pp. vii + 247. (London: Kegan Paul and Co., Ltd., 1932.) 12*s*. 6*d*. net.

LANGUAGE is viewed at an unusual angle in this work, which describes the interweaving of language with the other activities of mind. It is the philosophy rather than the analysis of language it presents. The author has striking conclusions to put forward on a variety of subjects such as "Language and Life", "Language and Nature", "Language and Science", "Language and Poetry", "Language and Religion". To quote but one of them, he thinks that mathematics might be called a language which allows only pronouns in place of nouns, imperatives in place of verbs, copulative equations instead of adjectives and adverbs. The purpose of mathematical co-ordination of language and concept is the liberation of the concept from the senses. But there is danger in an extreme liberation, because too much reason and abstraction scarcely allow thought to find the way back to itself.

Edmond Halley[*]

By Dr. Allan Ferguson

THE contributions of Shoreditch to the advancement of science are neither many nor varied; the occasional visitor to that cabinet-making region is usually drawn thither by the fame of the parish stocks and whipping-post, or of that oddly inscribed tombstone which marks Dr. John Gardner's "last and best bedroom". But the district has made one contribution of primary importance, for it was in the parish of St. Leonard's Shoreditch that Edmond Halley was born in 1656. Shoreditch was then a suburb of that pre-fire London of which so few traces remain. The London that Halley knew was a London cheerful, noisy and dirty, to modern eyes incredibly small, with narrow, fetid, kerbless streets and rat-ridden, overhanging houses; with a steep descent to the Fleet river, then practically an open sewer, where Holborn viaduct now stands; with an equally steep ascent to Tyburn along that *via dolorosa*, now called Oxford Street; with one ancient many-arched bridge joining the city to Southwark, its gateway crowned with frowning and blackened heads, its piers and starlings damming the river so effectively as to produce at certain stages of the tide several feet difference of level in the water above and below the bridge; with Whitehall still crossed by a Tudor gateway, and the banqueting house of Inigo Jones alive with recent memories of the royal execution.

The ghastly plague pit at Aldgate, hard by the Three Nuns hotel, comes clearly enough even now before the minds of those who turn eastwards from Houndsditch along the little alley that skirts St. Botolph's church, and swings southward through Church Row to join Aldgate. A Three Nuns' hostel still stands near the church, the graveyard of which is significantly raised some feet above the level of the surrounding streets. Pit, inn, church, and the vanished Pye Tavern "over against the end of Houndsditch" where an obscene crowd of roysterers was wont to gather and to jeer at the passing dead-cart must have been very vivid in the memory of Halley, who passed, apparently unscathed, through these fateful years. He was educated at St. Paul's School, under Dr. Thomas Gale, and at fifteen years of age was captain of the school. In 1673 he was admitted a student of Queen's College, Oxford, "having already acquired not only good skill in the Latin, Greek and Hebrew Tongues, but being also well acquainted in the Principles of Geometry and Astronomy, in which he . . . so early distinguisht himself, that we find a Piece of His, called, *Methodus directa et Geometrica cujus ope investigantur Aphelia, Excentricitantes, Proportionesque Orbitarum Planetareorum, absque supposita æqualitate Anguli motus ad alterum Ellipeos Focum, ab Astronomis hactenus usurpata*, . . . publish't in the *Philosophical Transactions* for the Months of August and September, 1676." Kepler had, as we know, enunciated many years before this date his laws stating that the path of a planet is an ellipse, with the sun in one focus; and that the motion of the planet round the sun is not uniform, but is such that the line joining sun to planet sweeps out equal areas in equal times. It was assumed, and it is in fact nearly true, that the motion about the empty focus of the ellipse was exactly uniform; that Halley, at nineteen, should be able to attack critically such a problem shows that he was already highly skilled in the use of the imperfect mathematical apparatus of his day.

Halley did not stay long enough at Oxford to take his degree. His was one of those prescient characters that realises almost instinctively the direction in which knowledge is advancing, and which field it profits best to cultivate. His tastes lay in the direction of astronomy, and he well knew that trustworthy star-charts were one of the pressing needs of the day. But several explorers, Flamsteed and Hevelius in particular, had already set out to chart the northern stars, and Halley, now a skilled mathematician and observer, knew the advantages of a clear field; he therefore decided to make a beginning in the southern hemisphere.

Halley's father, a wealthy London tradesman, settled on his son an allowance of £300 a year, and in 1676, armed with "an excellent brass sextant of 5½ feet radius, with Telescopic Sights and indented Semicircles of the same Metal, and Screws for the ready bringing it into any Plane; a Quadrant of about 2 foot Radius, which he chiefly intended for observations to adjust his Clock; a good pendulum clock; and a Telescope of 24 feet; some lesser ones; and two Micrometers", Halley set sail for St. Helena, where he had decided to set up his observatory.

The climate of St. Helena proved to be very much what it was a century and a half later when the island became the scene of Napoleon's exile. Nevertheless, though the skies were cloudy and rain frequent, Halley stayed there for about a year; and the title of the 'Southern Tycho' was given to him in virtue of his star catalogue, published in 1679.

In this last-named year, Halley embarked upon another adventure. To-day it appears absurdly obvious that far greater accuracy in determining stellar positions is obtained by sighting a star through a telescope than by using the naked eye and the sighting rods in the manner of the older astronomers. This was not so obvious in 1679; ordinary pinhole sights were certainly crude, but Tycho, one of the great pioneers in exact measurement, had improved this type of sight almost beyond recognition. An example of his measurements may serve to show the accuracy attainable by the use of naked eyesights. Tycho, alive to the necessity for accurate charting, selected seven stars, the most important of these being α Arietis, as standard stars, the positions of which on the celestial sphere he determined with the highest possible accuracy. These measurements of position must, of course, be made with reference to some definite starting point, and it is the intersection of the sun's apparent yearly path in the heavens with the equator of the celestial sphere which determines the position of the Greenwich of the heavens. Tycho's task, therefore, was that of linking up the position of the sun with that of any one of the selected stars. This was done by means of an intermediary, Venus, visible both in the daytime and at night. Tycho determined the relative positions of the sun and Venus, and afterwards of Venus and one of the selected stars, making due allowance for the motion of Venus in the period intervening between the two observations. Some notion of Tycho's accuracy may be gleaned from the fact that the Right Ascension (the analogue of terrestrial longitude) of α Arietis was fixed by him at a mean value of 26° 0′ 30″, the modern estimate for the year 1585 being 26° 0′ 45″. Dreyer gives the probable errors of the positions of Tycho's standard stars as ± 24″·1 in Right Ascension and 25″·9 in Declination (when corrected for refraction).

---

[*] "Correspondence and Papers of Edmond Halley." Preceded by an unpublished Memoir of his Life by one of his Contemporaries, and the 'Éloge' by d'Ortous de Mairan. Arranged and Edited by Eugene Fairfield MacPike. (History of Science Society Publications, New Series 2.) Pp. xiv+300+9 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1932.) 21*s*. net.

With possibilities of consistency in observing indicated by figures such as these, it is not surprising that older observers, cognisant of the crudity of the new telescopic sights, should elect to continue to make their observations by the older methods. Foremost among them was Hevelius of Dantzig and, the better to make a critical comparison of the two methods, Halley visited Dantzig in 1679. He was duly impressed with the skill displayed by Hevelius in the use of his instruments, and, in a letter to Flamsteed under date June 7, 1679, he says, after describing the equipment of Hevelius's observatory:—"... As to the distances measured by the Sextans, I assure you I was surpris'd to see so near an agreement in them, and had I not seen, I could scarce have credited the relation of any; Verily I have seen the same distance repeated several times without any fallacy agree to 10″, and on Wednesday last I myself tryed what I could doe, and first I at the moveable sight, and the Printer at the fixt did observe the distance of Yed Ophiuchi from Lucida Aquilæ 55°-19′-00″; then we removed the Index, and my Lord at the moveable sight and I at the fixt did observe the same 55°-19′-05″, and you will find the same distance 6 times observed in Page 272 of ye fourth book of his Machina Coelestis, so that I dare no more doubt of his veracitye." Nevertheless, Halley was too sagacious not to realise that ultimate victory lay with the users of telescopic sights. As for Hevelius, the writer of a memoir of Halley remarks that "the old Gentleman was too much rivetted to his Opinion of those he had so long and so successfully used; and had besides been too much sour'd by the manner in which Dr. Hooke had too freely treated his Labours to think of altering his method or opinion".

It is interesting to note that in a hitherto unpublished letter in the Royal Society's archives Halley, writing under date 1686 to Molyneux concerning "the state of the Controversy between Mr. Hevelius and Mr. Hook about Telescope Sights wherein I am so much concerned", remarks that this controversy "does, as Hevelius manages the matter, affect all those observers that use Telescope sights, and myself in particular, and it is our common concern to vindicate the truth from the aspersions of an old peevish gentleman, who would not have it believed that it is possible to do better than he has done".

Halley's next piece of sustained practical work lay in a study of the variation of the compass. Here again we see illustrated his habit of seizing on a pioneer piece of work, and rounding it off neatly and thoroughly. Provided with a vessel, the *Paramour Pink*—did ever other astronomer sail in so romantically named a ship?—Halley set sail in 1698. True to her romantic name, the ship was the scene of a mutiny, and Halley was forced to return to England. A mutinous lieutenant duly cashiered, Halley again set sail, this time accompanied by a consort, and returned the possessor of a unique mass of data, which he exhibited graphically after the modern manner, being in this matter again a pioneer.

Halley was appointed Savilian professor at Oxford in 1703, and in 1719, promoted to the position of Astronomer Royal, this indefatigable worker found himself in command of an observatory almost unprovided with instruments. He refurnished the observatory and optimistically set out at the age of sixty-three on an eighteen year cycle of lunar observations. He was, as ever, fortunate in his plan which he lived to complete, dying at the patriarchal age of eighty-five years. His interest in cometary orbits led him to study in detail the paths of several of these bodies and he concluded that the comets seen in 1531, 1607, and 1682 were not three separate bodies, but one and the same. The matter is, of course, considerably more complex than is indicated by a mere comparison of periods. Halley had, with immense labour, worked out the elements of the orbits of twenty-four comets. Three of these—those just mentioned—were sufficiently similar to make their identity probable, and this possibility was strengthened by the records of cometary appearances in 1305, 1380, and 1456. Nevertheless, the variations in the periods, and the differences in the inclinations of the orbits, amounting to as much as a degree, made recognition of their identity by no means certain. Halley was, however, too good a

Newtonian not to recognise that irregularities might be introduced by the gravitational pull of the giant Jupiter and, taking due cognisance of this, he ventured on his prophecy. "*Quo-circa,*" says he, "*si secundum predicta nostra redierit iterum circa annum 1758, hoc primum ab homine Anglo inventum fuisse non inficiabitur acqua posteritas.*" This prediction of its return in 1758, and its reappearance on Christmas Day of that year, near upon twenty years after Halley has been laid to rest in Lee Churchyard, is one of the dramas of the eighteenth century.

Halley, too, first showed from a comparison of ancient and modern observations that Aldebaran, Arcturus and Sirius had 'proper motions'.

Remarkable, however, as may be the sum of these achievements, his place in the history of the development of astronomical science depends largely on his friendship with Newton and on his connexion with the Royal Society. He was elected a member of that body in 1678, and in 1685, when one Mr. Aston resigned his position as secretary in something of a passion, the Council, in order to avoid future contretemps, decided to appoint a paid clerk who "shall be a single man without children . . . shall be master of the English, French and Latin tongues, . . . shall be able to write a fair and legible hand, and shall be completely seen in the Mathematics and Experimental Philosophy". His duties were carefully defined, and his emoluments fixed at £50 per annum at least, with a lodging in "the College where the Society meeteth". Halley was appointed to the position after a contested election.

About this period the inverse square law of gravitation was in the minds of many astronomers. Kepler had laid the foundations in the statements that :—

(*a*) The planets move in ellipses having the sun in one focus ;

(*b*) The radius vector sweeps out equal areas in equal times ; and

(*c*) For different planets, the squares of the periodic times are proportional to the cubes of their distances from the sun.

It is not a very difficult matter to deduce the inverse square law from Kepler's third statement, and Hooke, Halley and Wren had each, apparently, accomplished this feat. But the inverse problem—given the law of force, what will be the path of a planet ?—proved too much for all of them. In a well-known letter from Halley to Newton we find the statement that "in January 1683–4 I, having from the consideration of the sesquialterate proportion of Kepler, concluded that the centripetal force decreased in the proportions of the squares of the distances reciprocally, came on Wednesday to town (from Islington), where I met with Sir Christopher Wren and Mr. Hooke and falling in discourse about it, Mr. Hooke affirmed that upon that principle all the laws of the celestial motions were to be demonstrated, and that he himself had done it". In the same letter he chronicles an offer made by Wren in a sporting spirit which we do not usually associate with his name. We read that "Sir Christopher, to encourage the enquiry said that he would give Mr. Hooke some two months' time to bring him a convincing demonstration thereof, and besides the honour, he of us that did it should have from him the present of a book of forty shillings. Mr. Hooke then said he had it, but that he would conceal it for some time, that others trying and failing might know how to value it when he should make it public. However, I remember that Sir Christopher was little satisfied that he could do it, and though Mr. Hooke then promised to show it him, I do not find that in that particular he has been so good as his word".

It was Halley who took the problem to Newton, to find that Newton had long ago solved this and other problems of planetary motion, and it was Halley's enthusiasm that overcame Newton's constitutional aversion to publication, and drove him to put forward his views in connected form. On April 28, 1686, Dr. Vincent laid before the Royal Society the MS. of the first book of the "Principia", and on May 19 the Society resolved that "Mr. Newton's *Philosophiæ Naturalis Principia Mathematica* be printed forthwith in quarto in a fair letter". On June 2 we hear a different note ; the Council orders that "Mr. Newton's book be printed, and that Mr. Halley undertake the business of looking after it and printing it at his own charge" ; and Halley undertakes the task.

The Society was, in fact, in financial straits. It had, some time before, published "Willoughby de Historia Piscium", doubtless a learned volume, and one which then excited as much attention as a similar volume would do to-day. The Society made desperate efforts to minimise its loss, and the phrase "books of fishes" recurs in the Council minutes of the period like "the owercome o' a sang". The salaries of their officers fell into arrears, and the Council resolved to pay the unlucky philosophers in "books of fishes". Halley was agreeable ; Hooke more cautiously desired six months time to consider the acceptance of such payment ! Again, when the Society asked Halley to undertake the measurement of a degree of longitude, it was resolved that he "be given £50, or fifty books of fishes".

Newton, who could on occasion show what in a lesser man would be called peevishness, did not make Halley's task any easier by desiring to suppress the MS. of the third book of the "Principia", on hearing that Hooke was putting forward claims to priority. But Halley's perseverance triumphed over all difficulties and on July 5, 1686, the book received the *Imprimatur* of the then president, Samuel Pepys ; it was published about the middle of 1687.

Such is, in bare outline, the history of Halley's share in the publication of the "Principia". Rigaud does not put it any too high when he writes of "the immense obligation which the world owes . . . to Halley, without whose great zeal, able management, unwearied patience, scientific attainments, and disinterested generosity, the *Principia* might never have been published".

The book before us does not call for detailed review. It is a model of its kind, and, while not a life of Halley, it brings together a mass of material which, interesting in itself, should prove of immense value to any future biographer of Halley. The volume contains a memoir, possibly written by Martin Folkes, an *éloge* by de Mairan, a chronological list of Halley's correspondence, and a large quantity of hitherto unprinted letters and papers arranged in order of date. An appendix of about a hundred pages is concerned with a valuable series of Halleiana. Scholarly, relatively inexpensive, and well produced, the book should find a place on the shelves of every serious student of astronomy.

Recent Radio Research

THE Department of Scientific and Industrial Research has recently issued the report of the Radio Research Board for the year 1931,* summarising work carried out during the year. The investigations described are concerned mainly with the fundamental study of the electrical state of the upper atmosphere and its influence on the propagation of radio waves of all frequencies; the principles and improvements of method of radio direction-finding; the study of atmospherics from the point of view of radio communications and meteorology; the development of radio frequency standards; and the improvement of electrical measurements at high frequencies. This work is carried out mainly at the Radio Research Station, Slough, and at the National Physical Laboratory, Teddington, but a certain amount of research has also been fostered at universities.

The study of the ionisation of the atmosphere and its influence on the propagation of radio waves has been continued both by the frequency-change method which was originated in Great Britain by Prof. E. V. Appleton, and also by the pulse-emission or group-retardation method, first developed by G. Breit and M. A. Tuve in the United States. To assist in this investigation, which includes the systematic collection of data on the electrical properties of the upper atmosphere, a special transmitting installation has been designed and is in course of construction at the National Physical Laboratory. Concurrently with the experimental work, a theoretical analysis is being made of the effect of the upper atmosphere on radio waves, and the mathematical formulæ are being evaluated numerically for typical cases, so that the results can be used by the practical radio engineer. In all this work the effect of the earth's magnetic field is being studied, the necessity for this having been confirmed in an interesting manner in the year under review by experiments carried out in the southern hemisphere under the Australian Radio Research Board.

The report describes also the extension of the study of wave propagation to wave-lengths of less than 10 metres. In the first instance, the transmission of these ultra-short waves along the earth's surface has been investigated, and from the resulting measurements, values of the effective conductivity and dielectric constant of the earth have been obtained by wave-lengths between 1·6 and 10 metres. In addition, experiments have been carried out on a wave-length of 5·5 metres over a distance of 44 miles. In these experiments the absence of any downcoming radiation from the upper atmosphere was clearly indicated, and it was apparent that only the direct or ground waves were effective in securing communication, although the reception obtained was definitely not confined to the rectilinear or so-called 'optical' path between transmitter and receiver. Certain diurnal variations were found on hot, sunny days which were not experienced on dull, autumn days. The theoretical and practical investigation of the whole subject is being continued. Progress is also recorded in the study of improved means for generating electron oscillations giving rise to wave-lengths of less than 1 metre.

The report indicates that considerable progress has been made towards the development of the perfect direction-finder for medium wave-lengths, free from errors caused by downcoming waves occurring mostly at night. The behaviour of direction-finders on shorter wave-lengths is being studied, and the application of the cathode ray oscillograph to a direct-reading instantaneous direction-finder has met with considerable success. This is undoubtedly due to the large amount of experience previously obtained in the use of these instruments in the study of atmospherics at the Radio Research Station.

In the present crowded state of the ether, it is specially important that every radio station should accurately maintain its allotted wave-length or frequency. The precise measurement of frequency, therefore, has become of great practical importance. The primary national standard of frequency is maintained at the National Physical Laboratory, and, as the report explains, is based on a tuning-fork maintained in continuous and steady vibration. The rate of vibration of the standard tuning-fork is now directly referred to that of an astronomical clock by an electrical arrangement, and can be obtained accurately to within one part in ten million. Experiments are in progress to determine the short-period constancy of the fork, that is, the constancy for one or two minutes at a time. It is not easy to compare frequencies to an accuracy of one part in a hundred million during an interval of only one minute, but such tests as have already been made indicate that the fluctuations due to the action of the thermal regulation are less than one part in a hundred million.

---

* Department of Scientific and Industrial Research. Report of the Radio Research Board for the Year 1931. Pp. iv + 123. (London: H.M. Stationery Office, 1932.) 2*s*. net.

"Sufficient experience has now been accumulated," the report says, "to enable the statement to be made that properly designed and steadily operated tuning-forks form a primary frequency standard of reliability of about one part in ten million, a result fully equal to that of the best pendulum clocks. It is an interesting fact that the slight earthquake experienced in the south-east of England on June 7, 1931, caused a small change in rate of the pendulum clock of about four parts in ten million, which was revealed on the tuning-fork chronograph, the tuning-fork being unaffected by the shock."

It has now become necessary to develop apparatus to resolve the differences between the tuning-fork and the clock to enable short period fluctuations to be accurately observed. For this purpose radial vibrations of a small quartz crystal very carefully cut in the form of a ring are used to control the oscillation of a valve generator. The experiments carried out give good hope that a standard which is permanent and accurate to one part in a hundred million may be obtained in the near future.

The above review is by no means exhaustive of the contents of the report, which shows that the organisation controlled by the Radio Research Board continues the active pursuit of radio research and development, which in the past few years has placed Great Britain in a world-renowned position.

Obituary

PROF. JAMES JOHNSTONE

JAMES JOHNSTONE, the distinguished zoologist, oceanographer and philosopher, died at the age of sixty-two years at his home in Lochwinnoch on December 27 after a sudden attack of influenza. He appeared to have recovered from his former dangerous illness, so that his loss from an apparently accidental infection is felt the more keenly. He was not married.

There can be no doubt that he was a man of exceptional ability with an unusually wide knowledge of science; and a fearless and original thinker. Though reticent and even shy, "J. J.", as he was familiarly called, endeared himself to all those who had much to do with him by his kindly and sympathetic manner and his philosophical outlook on life's problems. It is characteristic of him that he was especially concerned about the future prospects of the junior staff and servants employed in his Department.

The future philosopher showed his naturalistic leanings as a boy when he roamed the country observing wild animals and collecting birds' eggs; he exhibited the urge of the 'vital impetus'—which was to concern him greatly later—when as a young man he 'emerged' from the environment of a journeyman wood-carver by attending evening classes at Lochwinnoch and at Glasgow. By the encouragement of his teacher and coach, Robert Logan, and the facilities afforded by the local school board and the Board of Education, he was enabled at the late age of twenty-five to begin the study of the biological sciences at the Royal College of Science, London, mainly under Prof. G. B. Howes. Before graduating in 1900 at the University of London he had already written one paper on the thymus in marsupials and two on fisheries subjects.

On his appointment in 1898 as fisheries assistant to Sir William (then Prof.) Herdman on the research staff of the Lancashire and Western Sea Fisheries Committee, Johnstone found a congenial environment; he threw himself with remarkable energy into studies in fisheries and the more general aspects of marine biology with such success that he had become a leading figure in British marine biology in 1908. This early success can be traced to his great interest in fisheries, to his unusually logical mind, and a great capacity for absorbing masses of data while perceiving and retaining a clear recollection of their interrelations, which he was able to expound in simple language. These faculties enabled him to bring together material on the growth and origin of "British Fisheries" (1905). The amassing of this material and his practical fishery experience placed him at once in a commanding position to give valuable support to the work of the newly instituted International Council for Fishery Investigations. The same faculties enabled him to produce an illuminating and classical work (1908) on "Conditions of Life in the Sea". This book was undoubtedly for many years a source of information and inspiration to the rising generation of marine biologists; in it he propounded a surprising proportion of the major problems which have been successfully investigated in recent years.

The basis of Johnstone's knowledge of fisheries lay in his experience in inshore and offshore work and the study of plankton in collaboration with his life-long friend, Andrew Scott. He also helped to lay the foundation for later successful work on the purification of shellfish. Marine bacteria were of great interest to him; his work led him to speculate on the existence in the sea of pathogenic types comparable with those found in terrestrial animals. He described a large number of malignant 'cancerous' tumours in fish, two of these being defined as of a "piscine tuberculosis" type, and accompanied these studies with extended investigations on parasites. His knowledge of this branch of pathology was associated with a vivid interest in human 'cancer', and its treatment by radium. Probably a real satisfaction in his life—betrayed in unguarded moments—was the success attending his share in the effort to procure radium for the Liverpool Radium Institute and Hospital for Cancer and Skin Diseases.

During the War, Johnstone's work on the dietetic value of fishes gained him an effective position on the Fish Preservation Committee of the Food Investigation Board of the Department of Scientific and Industrial Research.

In 1919, Johnstone was appointed lecturer in oceanography at the University of Liverpool and a year later he succeeded Sir William Herdman to the chair. In this new capacity he was fortunately able to indulge his leaning towards scholarship and philosophy. His works on oceanography brought up to date our knowledge of the physical features of the oceans; at the same time the story of the origin of the oceans is treated in a manner of fascinating interest to the students of geography and geology; "A Study of the Oceans" is indeed a new approach to the study of geography in a wide sense. Along with this work he undertook as director the reorganisation of the Port Erin Marine Biological Station and effected great improvements.

In later life the totality of the relations between things became to our savant—as to many other older scientific workers—of greater interest than lesser relations. He had already in 1914 surveyed the "Philosophy of Biology" and had stated the problems in his usual clear manner. These he elaborated later in "Mechanism of Life", and made what proved to be a final contribution recently in "Essentials of Biology" (1932). Here the fundamental problems of biology are discussed simply and logically with a rare clarity and impartiality. On the problem of the origin of life he refines his views of 1914 to the simple statement that ". . . it may be the case that the problem is only a pseudo one and that it is just as foolish to inquire into the origin of life as it would be to ask what was the origin of the universal tendency to entropy increase. We have no doubt that *the distinction between living and lifeless things is a problem for physics* [present writer's italics]. We have no confidence that the basal conceptions of physics have been established. That being so, it is futile further to continue this discussion".

On this problem—as on many others—the philosopher and research worker discloses the apparent inadequacies of present-day knowledge. In this way James Johnstone leaves his problems and work to posterity, with a satisfying and rare record of achievement; and better still, he leaves a memory of a loveable man, wise and humble, great and unassuming.

PROF. C. M. THOMPSON

CLAUDE METFORD THOMPSON, emeritus professor of chemistry of the University College, Cardiff, was born at Bridgwater in 1855, and was the son of Alexander and Eleanor Thompson. He died at Cardiff on January 4, 1933, at the age of seventy-seven years. Some of the following particulars of his career are from the *Western Mail*. Prof. Thompson was educated at University College, London; Trinity College, Cambridge, where he was a scholar; and the University of Bonn. At Cambridge he obtained the degree of M.A.; his D.Sc. was awarded to him by the University of London, which university also bestowed upon him a gold medal for distinction in his subject; and the University of Wales conferred upon him the degree of D.Sc. (*honoris causa*) for his services during and after its institution in 1893. He was the last of the original professors appointed in 1883 when the University College, Cardiff, was opened under the principalship of Viriamu Jones, and he retired from the service of the College in 1921, with the title of emeritus professor, after a successful career as professor of chemistry.

Dr. Thompson's assistance and advice to the University and the University College were particularly useful regarding the details of educational organisation and in the preparation of regulations, courses, and schemes of study for degrees. Up to the time of his death he was a member of the Court of Governors of the College, appointed by the Chancellor of the University of Cambridge. He found time to carry on research work, particularly into the constituents and possible uses of rare earths and their application to commercial products, such as incandescent mantles.

Dr. Thompson was a generous supporter of the University College at Cardiff, and the donor of many volumes and publications on chemistry to its library. In his early days he found his chief enjoyment in mountaineering during vacations; he was a member of the Alpine Club. He identified himself with local interests by becoming a member of the Cardiff Naturalists' Society, in the work of which he was particularly active. He took a keen delight in gardening, and many of the amenities to be found in "Cae Syr Dafydd", one of Cardiff's parks, are largely due to his care and attention. A. A. R.

WE regret to announce the following deaths:

Mr. T. H. Coward, a well-known naturalist and an authority on British birds, on January 29, aged sixty-six years.

Sir Percy Sargent, C.M.G., formerly surgeon to St. Thomas's Hospital and the National Hospital, Queen Square, London, and Hunterian professor of surgery and pathology at the Royal College of Surgeons in 1928, an authority on brain surgery, on January 22, aged fifty-nine years.

Dr. John Thomas, joint managing director of the Dyestuffs Group of Imperial Chemical Industries, Ltd., a well-known authority on dye-stuffs, on January 18, aged forty-six years.

News and Views

Dr. G. D. Hale Carpenter

The vacancy in the Hope professorship of zoology at Oxford, caused by the resignation of Prof. E. B. Poulton, has been filled by the appointment of Dr. G. D. Hale Carpenter. Dr. Carpenter is widely known for his investigation of the bionomics of the tsetse fly, *Glossina palpalis*, a work undertaken by him between the years 1910 and 1914. During this time he resided first at Jinja on the north shore of Victoria Nyanza, and afterwards on various islands, especially those of the Sesse archipelago, lying in the north-west corner of the lake. While the primary object of his living in this region was the study of the tsetse fly as the carrier of sleeping sickness, Dr. Carpenter found occasion to make many important observations on the natural history of the islands, especially in regard to the remarkable phenomena of mimicry shown by the swallow-tail butterfly, *Papilio dardanus*, and the series of forms of the nymphaline *Pseudacraea eurytus* mimicking the acraeine genus *Planema*. At the outbreak of the War, he was called upon to act as medical officer to the forces operating on the southern frontier of Uganda, in German East Africa and Portuguese East Africa; and amidst the duties of active service he found opportunities for further fruitful observation, opportunities which were increased and turned to fresh account on his return to Uganda in 1918. His book "A Naturalist on Lake Victoria" was published in 1920. Dr. Carpenter's work has throughout been influenced and inspired by Prof. Poulton; and there is every reason for anticipating that the traditions of the Hope Department will be worthily carried on by the new professor.

Pierre André Latreille

Pierre André Latreille, the brilliant French naturalist, who devoted himself to the study of entomology and made considerable additions to our knowledge of that branch of natural science, died in Paris a hundred years ago on February 6 at the age of seventy-one years. Latreille was born on November 29, 1762, at Brive-la-Gaillarde, in the department of Corrèze. At the age of sixteen years he entered the Collège Lemoine, Paris, where he studied for the church. After he had taken orders in 1786, he retired to Brive, where he devoted himself chiefly to the study of insects. He returned to Paris in 1788, and during the Revolution was imprisoned at Bordeaux; but was released on account of the interest shown in his entomological studies. His great work, "Précis des Caractères génériques des Insectes, Disposés dans un Ordre naturel"—an important step towards a truly natural system of entomology—was published in 1796, and led to his being appointed to arrange and take charge of the entomological collection at the Muséum national d'Histoire naturelle (Jardin des Plantes) in Paris. He became professor of natural history at the Museum in 1830, and succeeded Lamarck as professor of zoology. Latreille wrote the entomological part of Cuvier's "Règne Animal". His other important works are "Salamandres", "Singes", "Crustacés et Insectes", "Reptiles", "Genera Crustaceorum et Insectorum", "Considerations générales sur l'Ordre naturel des Animaux", "Familles naturelles du Règne Animal", and "Cours d'Entomologie".

Geological Society Awards

The Council of the Geological Society of London has made the following awards for this year: *Wollaston Medal*, to Prof. Marcellin Boule, professor of palæontology in the Muséum national d'Histoire naturelle, Paris, in recognition of the value of his researches concerning the mineral structure of the earth, and especially for his contributions to the geology and vertebrate palæontology of the Tertiary period; *Murchison Medal*, together with an award from the Murchison Geological Fund, to Dr. A. L. Du Toit, consulting geologist, Johannesburg, in recognition of the value of his work, especially on the geology of South Africa; *Lyell Medal*, together with an award from the Lyell Geological Fund, to Mr. J. E. Richey, Geological Survey of Great Britain (Scottish Office), for his researches in the Tertiary volcanic geology of the British Isles; *Bigsby Medal*, to Mr. E. J. Wayland, director of the Geological Survey of Uganda, in recognition of the value of his geological researches, particularly in Uganda; *Wollaston Fund*, to Mr. A. Wrigley, for his work on the Tertiary Mollusca of the London district; *Murchison Fund*, to Mr. T. H. Whitehead, Geological Survey of Great Britain, in recognition of the value of his work on the Carboniferous and older rocks of the Midlands; a moiety of the *Lyell Fund* to Mr. A. Broughton Edge, in recognition of the value of his geophysical work in application to geological problems; a second moiety of the *Lyell Fund*, to Mr. W. N. Edwards, Natural History Museum, in recognition of the value of his researches on fossil plants.

Stoke Park (R. G. Burden) Fund for Research in Mental Disorders

Mrs. R. G. Burden, of Clevedon, Somerset, has offered a sum of £10,000 for research into mental problems and disorders, suggesting that Prof. R. J. A. Berry, Director of Medical Services, Stoke Park Colony, Stapleton, Bristol, shall have general control of the investigations. In view of the munificence of this donation and the importance to the nation of its objectives, it has been deemed advisable to form a strong and nationally representative committee of administration. This committee will be responsible for the general direction of the research, the appointment of the research staff, the determination of salaries, and the publication, from time to time, of such reports as it may think fit to issue. Arrangements have already been made for the representation on this committee of the Ministry of Health (Board of Control), the British Medical Association, the

Francis Galton Laboratory for National Eugenics at University College, London, the Royal Medico-Psychological Association, the Central Association for Mental Welfare, and for other representative individuals specially selected for their scientific or medical attainments. In accordance with the terms of the bequest, Prof. R. J. A. Berry will act as chairman of the committee, which will meet in London at the house of the British Medical Association, with Dr. G. C. Anderson as its honorary secretary. As the committee has not yet met, nothing has been determined as to the nature of the researches to be carried out, though doubtless one line of approach will be the hereditary transmission, or otherwise, of mental deficiency and other disorders. Applications will shortly be invited for a specially selected team of investigators, particulars of which will be made known later.

Preliminary Tests for Everest Flight

A WESTLAND *PV*–3 type two-seater biplane, named the *Houston-Westland*, fitted with a Bristol Pegasus *S*.III engine, piloted by Mr. H. J. Penrose, test pilot at the Westland Aircraft Works, reached a height of 35,000 ft. at Yeovil on Wednesday, January 25. The total time in the air was about 1 hr. 40 min. This constitutes a world's record for a two-seater aircraft. This machine has been specially adapted to undertake a flight over Mount Everest in conjunction with an expedition led by Air-Commodore P. F. M. Fellowes, with Lord Clydesdale as pilot. Specially designed electrical heating apparatus includes not only heated clothing, but also warming devices for the cabin, the valves of the oxygen apparatus for breathing, many of the instruments and jackets for the cameras. The pilot's cockpit is a normal open one, but is fitted with a hooded windscreen as a protection against draughts. The observer's cockpit is roofed over and is provided with sliding windows in either side and the floor for photographic purposes. Williamson Eagle cameras and cinematograph apparatus are to be used. The machine weighs about 5,000 lb. fully loaded as for the Everest flight, and, as is usual with supercharged engines, carries a propeller that allows the full horse power to be developed only after passing 13,000 ft. height. Temperatures down to −40° C. were registered inside the observer's cabin at the extreme altitude reached. The elimination of vibration, to assist the photography, has been specially dealt with, and in this respect the flight was very successful. A second machine is being converted similarly to take part in the expedition.

Aircraft in Relation to Petroleum Technology

THIS subject has recently received a good deal of technical and non-technical publicity, both in Great Britain and abroad. Resulting from the extensive use of aeroplanes during the War for reconnaissance and survey purposes, aircraft operations afterwards gained a firm foothold in the technique of exploration, particularly in inaccessible territory. Developments were rapid and the applications to map-making were perfected and commercialised. The incidence of aircraft as an important factor in geological studies is of more recent date and primarily owes its recognition to the important work carried out in North and South America in connexion with exploration for petroleum, including the survey of pipe-line tracks. Both in the realm of petroleum technology and mining geology, aerial reconnaissance and photography have proved valuable as time- and money-saving factors. The literature on this aspect of the subject has grown extensively during the last few years, and probably one of the most complete accounts of the subject was given by Mr. Donald Gill before the Institution of Mining and Metallurgy recently, when he dealt with "Aerial Survey in Relation to Economic Geology". This paper contains a useful bibliography, which has been reproduced with additions by Mr. H. Hemming, who discussed the commercial aspects of the subject at a meeting of the Institution of Petroleum Technologists on January 10. Mr. Hemming showed clearly that the main value attached to the use of aircraft in exploratory work is for obtaining rapidly information of technical value, and for transporting personnel or material from one place to another. He gave a very succinct account, not only of what has already been accomplished in this direction, but also of the potentialities of further development of air survey.

Empire Broadcasting

SINCE the opening of the Empire Broadcasting Station at Daventry on December 19 (see NATURE, 131, 16, Jan. 7, 1933) the British Broadcasting Corporation has received a large number of cablegrams reporting reception of the transmissions in all parts of the world. A very large number of letters has also been received from listeners, and extracts from some of these are published in recent issues of *World Radio*, which is now the official organ of Empire broadcasting. Good quality reception is reported from such places as Bagdad, the Federated Malay States, Zululand, Tanganyika, various parts of India, New Zealand, and North and South America. In some places, particularly South Africa, local atmospheric conditions have marred the reception to some extent, but on the whole it would appear from the first few weeks' tests that the inauguration of the new Empire broadcasting service has been a conspicuous success. The aerial arrays and the transmitters for the Empire Broadcasting Station at Daventry were designed, constructed and installed by Messrs. Standard Telephones and Cables Ltd.

Anthropological Survey of Ireland

A FIVE-YEAR plan for an anthropological survey of Ireland has been formulated by anthropological members of Harvard University. It will cover the archæology, social anthropology and the physical characters of the Irish people. In a preliminary account and progress report of the survey (*Science*, vol. 76, No. 1978) its object is said to be "to produce some sort of scientific interpretation of the Irish people". The proposal has been cordially received in Ireland, and now has the official approval of the President of the Irish Free State. The archæological section of the expedition is already at work and during the past summer, under the leadership of Dr. O'Neil Hencken and under the auspices of the National Museum of Ireland, has been engaged in the excavation of a Viking age crannog at Ballinderry, Co. Westmeath, and of bronze age burials nearby at Knockast, with remarkable results. For the study of social anthropology, Co. Clare has been chosen as the area affording most typically a blend of the old and the new in Irish culture. A preliminary survey has been made by Prof. W. Lloyd Warner, assistant professor of social anthropology in Harvard University, assisted by Mr. Conrad Arensburg, post-graduate anthropological student of the University. It is intended to devote two years with an extended staff to the observation of every aspect of Irish social life. Physical anthropology will be under the charge of Prof. E. A. Hooton, of Harvard University, who will also be responsible for the general oversight of the work of the expedition.

Excavation in Alaska

DURING the past summer an expedition of the University Museum of Pennsylvania, conducted by Miss Frederika de Laguna, has been at work on the coasts of Alaska in conformity with the policy of American anthropology for the intensive study of this area in relation to the problem of the early peopling of America. The expedition was engaged in the excavation of a prehistoric village site in Kachemak Bay, Cook Inlet. Of the finds of the season, Science Service (Washington D.C.) reports that Miss de Laguna regards the outstanding object to be a carved stone lamp. In the bowl of the lamp is a human figure in an attitude of prayer carved in full relief. Four other examples of such lamps are known ; but this is the only example to be found by a scientific explorer *in situ*. It is said to come from the last phase of four prehistoric Eskimo settlements ; but although the early phase of the 'archaic' culture of the area is remarkable for its carved ivories, stone carving is not known as an Eskimo technique. The lamp was found in a shell-heap close to the sea, which is washed by high tide. Other cultural features of the same settlement were slate mirrors, slate blades for lances, bone harpoons and dart heads, grinding stones, awls, drills, dolls, beads and needles. Rock-paintings were found in caves. Such paintings are known only in southern Cook Inlet and on Kodiak Island, where the culture is similar. The Indians of to-day believe that these pictures were painted by 'whale killers', much feared medicine-men who poisoned their lances with human fat. If there were any foundation for this belief, it might be related to the traces of cannibalism found in prehistoric settlements by the Smithsonian Alaskan expeditions.

Spelling of Place Names

THE United States Geographic Board has published a "First Report on Foreign Geographical Names" (Washington Government Printing Office, 1932. 10 cents). The list of names is prefaced by a long discussion of the problems involved, which is followed by certain general rules that the Board has adopted. The conventional English usage is adopted for the names of countries, dominions, colonies, etc., and for geographical features common to several States in which the official languages are different. For local geographical names in States where a Latin alphabet is used, the names are spelled in accordance with local usage but conventional English forms, where such exist, are accepted as alternatives. Names in non-Latin alphabets are to be transliterated according to either official transliteration, where such exists, or a system adopted by the Board and printed in this report. The practice of translating names is discouraged. The policy adopted by the Board differs little from that used by the Permanent Committee on Geographical Names for British Official Use. The differences lie in the spelling of names in possessions of European powers and in the transliteration of 'j' and 'zh' in certain languages, but it is laid down that in the absence of any specific decision of the United States Board, the decision of the British Committee is to be followed in certain cases. The actual list of names in the Report gives pronunciation in many cases but omits it in several names where its addition would certainly be useful.

Forest Fires in Japan

A PAPER on "Forest Fires and Weather" (*Sci. Papers Inst. Phys. Chem. Res.*, Tokyo, vol. 18), by T. Terada and T. Utigasaki, states that the annual loss due to forest fires in Japan is second in magnitude only to that suffered by the United States. Japanese meteorologists might therefore do good service by studying the weather conditions that precede these fires in Japan, and perhaps eventually organising a system of warnings, following the example of the United States. The authors of this paper were led to study this subject with the aid of synoptic weather charts through the known tendency for the fires to break out practically simultaneously in widely scattered parts of Japan. They conclude that such outbreaks are generally associated with the near approach of the 'squall-line' or principal cold front of a depression following an easterly track north of Japan, when the warmer of the two wind currents yields maximum temperatures of 20° C. or more. There seems no *a priori* reason why the front should have anything to do with the matter ; it is easy to imagine that the necessary antecedent conditions are merely a sufficiency of wind and warmth, with no rain and perhaps some special state of the air in regard to its water-vapour content. These conditions might seldom occur except on the approach of a depression. As frequently happens with investigations in which synoptic charts are used, the extent to which the evidence supports the conclusions cannot be gauged accurately unless all the charts are reproduced in great detail. It must have been difficult for the authors to determine the position of the front in relation to the outbreaks, seeing that they had to rely upon newspaper reports for the times of the outbreaks.

The Disturbing Influence of Science

LECTURING to the Science Federation of the University of Manchester on January 23 under the title "The Irresponsibility of Science", Prof. H. Levy asserted that the problems of unemployment and the distribution of leisure are problems which the man of science must help to solve. It is part of the duty of the scientific man to examine the external properties of science and to face the ethical problems which the application of scientific discoveries is liable to create. The habit engendered in the scientific worker by his very method of endeavouring to isolate objects or causes and consider the influence of single factors in a problem has a very real danger in that it leads scientific workers to assume that all scientific questions are independent of ethics. Practically all scientific work, however, has a social aspect and its social properties cannot be clearly separated from its scientific properties any more than theoretical and applied science can be sharply demarcated. At the present time we are being forced to consider indeed the limit beyond which the process of improving the weapons of production is likely to disturb the structure of the original scientific movement itself. The scientific worker cannot ignore the fact that in practice what is intended as a gift of more leisure for all becomes unemployment and loss of consuming power for some. Scientific men must endeavour to find what factors go to the creation of an unstable society under the impact of science in this way. Prof. Levy suggested that scientific men should analyse the tendencies of science so that they could direct them. Science, which has been a revolutionary factor, has now become a disturbing factor in the world, affecting the stability of communities, and the study of that disturbance is one for international science.

Science and the Textile Industry

SPEAKING on January 26 on the textile industry in the course of lectures on industrial affairs which are being given to the students of the Imperial College of Science and Technology, Dr. Kenneth Lee expressed his belief that the rapid development of scientific research will prove the best investment the textile industry can make. The British Cotton Industry Research Association has undoubtedly the best equipped textile research institute in the world, but although about eighty per cent of those engaged in production contributed to it, in relation to the magnitude of the industry the amount subscribed is negligible. Dr. Kenneth Lee believes that if the necessary financial support is forthcoming, we could dominate to a large extent the cotton textile field in the production of new inventions during the next few years. In addition to utilising science, the cotton industry must also employ men in its mills who can understand the work that science is doing. Dr. Kenneth Lee referred in particular to the way in which science, by introducing means of artificial humidification and ventilation, has not only discounted what was once supposed to be a great advantage of the Lancashire industry—its damp climate—but has made it possible to obtain uniform conditions throughout the year with higher output and more efficient use of automatic machinery.

Direct-Current Generators for Electrostatic Precipitation

IN the English Electric Co.'s *Journal* for October, a description is given of the high-pressure D.C. dynamos it constructs for use in electrostatic precipitation plant. The Whessoe Foundry and Engineering Co., Ltd., specialises in apparatus for fog and mist extraction, and the English Electric Co.'s dynamos are specially designed to work with its plant. The removal of suspended particles from large volumes of gas is an important commercial problem at the present time. Electrostatic precipitation is now regarded as the most efficient and economical method for cleaning gases. The English Electric Co. has designed many high-pressure D.C. machines for radio transmission purposes, and the new dynamos are based on the experience gained in radio work. The generating unit for a typical equipment has to supply a current of about 0·15 amperes at a pressure of 45 kilovolts. The unit consists of a driving motor made to suit the local supply, coupled to three generators connected in series. The frames of the machines are insulated from the earth by individual supports of solid porcelain. The whole of the high-pressure apparatus is enclosed by screens which separate it from the driving motor and prevent unauthorised access. A simple interlock on the door renders it impossible for anyone to enter the high-pressure compartment when the generators are running. As a further precaution, every conductor which is at high pressure when the machine is running is connected with the earth when the set is at 'standstill'. Accidental shocks are thus avoided. A notable feature of the set is its ability to withstand a short circuit without a 'flash-over'. A model precipitation equipment was shown in action at the English Electric Co.'s exhibition last November.

Ship Researches at the William Froude Laboratory

DURING the last ten or twelve years, no fewer than twenty-two papers have been contributed to the transactions of the Institution of Naval Architects, the North-East Coast Institution of Engineers and Shipbuilders and other bodies, by the members of the staff of the William Froude Laboratory, National Physical Laboratory, Teddington. Among these papers are six on the effect of weather conditions on the propulsion of ships, seven on the manœuvring of ships and six on the efficiency of screw propellers. The other papers deal with the hulls of flying boats and ship propulsion data. Needless to say, all the papers are of permanent value and they have now been re-issued as vol. 23 of the Collected Researches of the National Physical Laboratory (London : H.M. Stationery Office. 20*s.* net). Arrangements have also been made to publish them in five groups. Each paper is preceded by a short abstract and the volume has an adequate index, but the reprint does not contain reports of the discussions, for which reference will have to be made to the transactions of the various societies. The majority of the papers, of course, deal with investigations carried out with models in the Alfred Yarrow Tank, but three of Mr. Kent's papers on the effect of weather conditions on the propulsion of ships contain his observations made on several voyages across the Atlantic in rough weather, when the routine of the laboratory was abandoned for all the discomforts of the sea.

Recent Acquisitions at the Natural History Museum

THE skin and skull of a hybrid between a lion and a leopard, which was bred in the Gardens of Kolhapur, has been presented to the Department of Zoology by Col. F. W. Wodehouse. This specimen, which had reached the age of three years, resulted from a union between a male leopard and a lioness, there being two cubs in the litter, the other one dying when about two and a half months old. These appear to be the only hybrids between a lion and leopard ever recorded. Among a small collection of mammals from Tanganyika Territory collected and presented by Mr. W. G. Cubitt-Currie is a new species of golden mole belonging to the genus *Chlorotalpa*. Purchases for the Department of Zoology include a specimen of the giant squid, *Architeuthis*, stranded in West Bay, Scarborough, on January 14. It is about 20 feet in length, including the tentacles. A notable addition to the Department of Geology is a complete specimen of the ancient shark, *Hybodus Lauffianus*. This is no less than seven feet long, and was discovered in the Upper Lias of Hobzmader, Württemberg. As with some specimens of *Ichthyosaurus* and other creatures found at this famous locality, not merely the skeleton, but also soft tissues, notably the skin, are present. The Department of Botany has received from the Godman Trustees a further collection of 848 specimens of flowering plants collected by Mr. R. G. N. Young in the Lunda province of Angola. The whole collection forms a valuable addition to our knowledge of the flora of this part of Angola and is especially noteworthy on account of the wealth of material of aquatic species. Amongst the purchases are 540 specimens collected in Brazil by B. H. Krukoff and a further series of 268 type specimens of the liverwort family Jubulearum.

Farmers' Guide to Agricultural Research

THE Royal Agricultural Society of England (16 Bedford Square, W.C.1) has issued the seventh of its series of annual summaries of scientific and economic research (1*s*. 3*d*. post free). The volume deals mainly with work carried out in Great Britain but also includes the results of colonial and foreign investigations so far as they have a bearing on British agriculture. This year the publication has been issued under a new title, namely, "The Farmer's Guide to Agricultural Research in 1931" in place of "Agricultural Research", by which it has been known hitherto. The change has been made in order to emphasise the main object of the publication, which is to provide the farmer with the most up-to-date information in all the leading branches of agriculture in a summarised and simple form. Apart from the title, the character of the volume remains unaltered, except that the section on crop and plant breeding is temporarily suspended and a new section on pests and parasites is included. The remaining sections, on dairy farming and dairy work, prevention and treatment of diseases of animals, farm economics, the feeding of live stock, farm implements and machinery, and soils and manures need only be cited to show how wide is the field of inquiry covered. Since each section is prepared by a recognised authority on the subject, the publication cannot fail to be of interest and practical value to the farmer, agricultural organiser and student.

Trout Fishing in New Zealand

AN interesting communication on the effects of intensive angling on the depreciation of trout-fishing in the Oreti (or New River) in New Zealand is given by Prof. E. Percival in Fisheries Bulletin No. 5 of the New Zealand Marine Department. The European trout when introduced into New Zealand showed remarkable fitness to their new environment by their great growth and in the early years afforded excellent opportunities for anglers. In recent years, however, there have been signs that the fishing is falling off to a considerable extent. This had been popularly attributed to a number of causes, such as the removal of the bush, leading to a decline in the food supply, the destruction of grasshoppers and cicadas by imported birds, or a change in the growth rate of the fish themselves. By examining old anglers' diaries, studying the food supply and growth of the trout, and using the statistics of angling societies, the author has shown that in all probability the decline in the fisheries is due to the great increase in the number of anglers themselves in recent years and to the opening up of fresh regions made accessible by modern rapid means of transport. The apparent decrease in size attained by the fish is due to the killing off of the older fish and the rapid removal of the smaller fish before they have time to reach a large size. In this publication Prof. Percival gives some valuable information on the food relations in inland waters of New Zealand, following up the work he has already done on the fauna of the streams of Great Britain.

Tests of Hearing

A COMMITTEE of the Section of Otology of the Royal Society of Medicine which was appointed in 1929 to consider tests of hearing has now issued its report (Longmans, Green and Co., Ltd., London. 2*s*. 6*d*.). Tests of hearing by tuning forks, which are widely used, were first considered. It was found, however, that there is no uniformity in the kinds or construction of forks employed by otologists. The Committee obtained the advice of Sir William Bragg and a list of requirements was formulated which was laid before Drs. Kaye, Dye, and Davis of the National Physical Laboratory, who undertook to draw up specifications for the manufacture of standard forks, and Messrs. J. and W. Ragg of Sheffield have completed a set which will shortly be available. The chief features of the standard fork are (1) the place where it should be struck is marked, (2) overtones should be inaudible within ten seconds of the fork being struck, (3) the pitch audible through air and bone to be the same, and (4) the rate of decay shall be such that the half intensity period of the vibrating fork in air shall be between three and ten seconds. Recommendations on the use of forks are given, the classical qualitative tests of hearing are surveyed and their clinical significance stated, and quantitative tests are discussed. Several memoranda on various aspects of the subject are contained in an appendix. The report is one of considerable value and interest.

American Association for the Advancement of Science

On December 30 the following officers of the American Association for the Advancement of Science were elected: *President:* Dr. Henry Norris Russell, Princeton University; *Permanent Secretary:* Prof. Henry B. Ward, University of Illinois; *General Secretary:* Prof. Burton E. Livingston, Johns Hopkins University; *Treasurer:* Mr. John L. Wirt, Carnegie Institution of Washington. *Vice-Presidents and Chairmen of Sections:* A (Mathematics), Prof. C. N. Moore, University of Cincinnati; B (Physics), Dr. C. J. Davisson, Bell Telephone Laboratories; C (Chemistry), Prof. Arthur B. Lamb, Harvard University; D (Astronomy), Dr. V. M. Slipher, Lowell Observatory; E (Geology), Prof. Rollin T. Chamberlin, University of Chicago; F (Zoological Sciences), Prof. A. S. Pearse, Duke University; G (Botanical Sciences), Prof. K. M. Wiegand, Cornell University; H (Anthropology), Prof. T. Wingate Todd, Western Reserve University; I (Psychology), Prof. Walter R. Miles, Yale University; K (Social and Economic Sciences), Dr. Wesley C. Mitchell, Columbia University; L (Historical and Philological Sciences), Mr. Waldo G. Leland, American Council of Learned Societies; M (Engineering), Mr. C. F. Kettering, General Motors Corporation; N (Medical Sciences), Prof. Charles R. Stockard, Cornell University; O (Agriculture), Mr. A. R. Mann, Cornell University; Q (Education), Prof. Walter F. Dearborn, Harvard University.

Announcements

It is announced that Sir Charles Reed Peers, president of the Society of Antiquaries, has been appointed a trustee of the British Museum in succession to the late Viscount Dillon, who died on December 18.

The Council of the Institution of Naval Architects has awarded the premium for the year 1932 to Dr. G. Kempf, and Herr H. Lerbs, of the Hamburg Experimental Tank, for their joint paper: "Cavitation Experiments on a Model Propeller".

At the meeting of the London Mathematical Society on February 16 at 5 P.M. at Burlington House, Prof. P. A. M. Dirac will deliver a lecture on "The Relation between Classical and Quantum Mechanics". Members of other scientific societies are invited to attend the lecture.

At the ordinary scientific meeting of the Chemical Society held on January 19 the President announced that Prof. S. Sugden had been appointed honorary secretary until the annual general meeting on March 30, and that the Council had nominated Prof. G. T. Morgan to the office of president and Prof. S. Sugden and Dr. J. M. Gulland as honorary secretaries to fill the vacant places that fall due to be filled at the annual general meeting.

The Council of the National Institute of Agricultural Botany has awarded the Snell memorial medal for 1932 to Dr. Kenneth M. Smith, entomologist of the Potato Virus Research Station, University of Cambridge. The medal is given to mark eminent work in the sphere of potato husbandry and it has been awarded to Dr. Smith in recognition of his valuable research work on the virus diseases of the potato. This has not only thrown much light on the methods of transmission of these diseases but has also had far-reaching influences on the whole plant virus problem.

As a result of further conferences between the "Dechema" (Deutsche Gesellschaft für chemisches Apparatewesen), the Verein deutscher Chemiker, the Verein deutscher Maschinenbauanstalten and the civic authorities of Cologne, it has been decided that, without interfering with the preparations in hand for the chemical plant exhibition "Achema VII", the date should be changed. The date for the exhibition, which will be held in Cologne, has therefore been finally fixed for May 18–27, 1934. The exhibition "Kautschuk" of the German Society for Rubber Industries which was to be held in conjunction with "Achema VII" will take place independently during 1933 in Cologne.

Applications are invited for the following appointments, on or before the dates mentioned :—Lecturers and instructors in various scientific subjects in evening institutes of the London County Council—The Education Officer, The County Hall, London, S.E.1 (Feb. 10). An Esher research student to carry out research in the history or archæology of London—The Secretary, London Museum, Lancaster House, St. James's, London, S.W.1 (March 11). A professor of agriculture at the University of Reading—The Registrar. An engineering workshop instructor and lecturer in workshop processes, drawing, calculations and science at the Borough Polytechnic, Borough Road, London, S.E.1—The Principal.

The Whale Shark in the Waters Around Ceylon

FROM time to time since 1862, whale sharks have been reported from the waters around Ceylon. In addition a number of incidental accounts based on erroneous identifications have been published. In the progress of an article on the geographical distribution of this great fish, these references have been looked up and it now seems a good opportunity to set forth the accurate accounts and designate those which are erroneous.

The earliest reference of all is that by Capt. James Steuart in 1862[1]. In writing of the pearl fishery, he noted that sharks were common and specifically stated that " . . . on two occasions my attention has been called to spotted ones of such monstrous size as to make the common ones at their sides appear like pilot-fish".

In 1883, and again in 1884, Haley[2] recorded the capture, at Moratuwa near Colombo, of a comparatively small specimen (23 ft. 9 in. long). This was mounted and is on exhibit in the Colombo Museum; for a figure of this see Gudger[3], 1931, pl. xxx. Haley[2] also recorded (1890) the capture in 1889 of an 18-ft. specimen at Ngombo, on the western shore just north of Colombo. The skin was sent to the British Museum and mounted; for figures of it, see Günther[4] (1889) and Gudger (1931, pl. xxxi). Lastly, Thurston[5] (1894) stated that in April, 1890, another small fish (14·5 ft.) was taken off Bambalapitya. I have been unable to identify this locality, but it is interesting to note that the other two specimens came from the west coast, and that all three were relatively small fish.

These are the substantiated records for Ceylonese waters. Other specimens of the whale shark have been taken off the Indian peninsula not far away. They will be noted in the paper on the distribution of the fish, but in the present article two indefinite and, in my judgment, erroneous references to the presence of this shark in Ceylonese waters must be cleared up.

The first of these is in A. E. Shipley and James Hornell's "Further Report on Parasites Found in Connection with the Pearl Oyster Fishery at Ceylon" (in W. A. Herdman's Report to the Government of Ceylon on the Pearl Oyster Fishery of the Gulf of Manaar, 1905, vol. 3, pp. 53 and 54). On page 53, they listed a trematode "from either a species of *Carcharias* or *Rhinodon typicus*, the 'basking shark' of tropical waters". Here already doubt was expressed and in a footnote the authors showed further doubt as to what is meant by the "basking shark". Herdman's recollection was that "the term was applied by the sea-going men to a *Carcharias*". Now, the form and coloration of the whale shark are so remarkable that no one who has seen even a good figure of it could ever mistake another shark for it. Moreover, the note further stated that such a "basking shark" caught on the pearl banks was sent to Boulenger who identified it as *Stegostoma tigrinum*, a shark somewhat similarly marked.

On page 54, Shipley and Hornell described a *Distomum* "taken from the perivisceral cavity of *Rhinodon typicus*". Here again I doubt the identification of the shark. On this point it should be noted that James Johnstone[6], in his report on the fishes taken by Herdman and Hornell, made no reference to such a shark—the capture of which would have been a notable matter. Further negative evidence will now be submitted.

Thomas Southwell[7], in his "Notes on the Food of Certain Marine Fishes of Ceylon" on page E 49, wrote: "*Rhinodon typicus.* March 14, 1910. One specimen. Stomach empty." Again, in his "Notes on the Fauna of the Ceylon Pearl Banks",[7] on page E 44, under date of March 18, 1910, of trawling in Dutch Bay, he wrote thus: "*Rhinodon typicus.* Stomach empty, but six huge cestodes in gut. Very ripe ovary. Oviduct full of eggs, 16 cases counted, same form as in dog-fish."

These statements interested me because they apparently gave two other records for *Rhineodon* off Ceylon, and particularly because one account indicated the method of reproduction in this rare shark. To verify and clear this matter up, I carried on an extensive correspondence with Mr. Southwell and with Dr. Joseph Pearson, director of the Colombo Museum. Southwell thought that the egg-cases were preserved in the Colombo Museum, but an exhaustive search by Pearson failed to reveal them. Then I turned to the question of identity of the shark. Pearson stated that in long years of trawling with literally thousands of hauls, neither he nor any of his men had ever seen a *Rhineodon*, which he knew well but thought a very rare fish around Ceylon. He suggested that Southwell's shark might be a *Stegostoma*, as Herdman indicated for a similar case above referred to. Southwell replied that he knew *Stegostoma* well and that it was not his fish, that he thought that his identification was correct since it was made from Day's "Fishes of India" (1889, vol. 2, p. 29), but that he might have been mistaken. Now the description of *Rhineodon* on the page cited in Day is so indefinite that it might be applied to almost any of several large barred and spotted sharks. My conjecture is that Southwell's shark might have been a *Galeocerdo tigrinum*. I think that it could not have been a whale shark. Had he seen this shark, its great size and extraordinary markings would most surely have fixed themselves in his mind.

I think that both these references to *Rhineodon* may safely be set down as due to mistaken identifications, and hence may be disregarded in this faunal survey. However, there are left the records of three specimens seen by scientific men, and in addition, Steuart's short account of his encounters with great spotted sharks, which were undoubtedly Rhineodons.

Properties of X-Radiation

The published accounts of unsuccessful attempts to find the J-phenomenon seem to call for some statement of the present position of investigations on the subject. Our experience of the phenomenon is now so extensive, that the comments and suggestions of experimenters are to us of little more than psychological, or shall we say philosophical, interest. Their results represent, at most, an almost negligible number of observations under conditions which we are able to reproduce at any time; they add nothing to our knowledge.

These negative results, that is results showing no J-discontinuity, are neither more nor less accurate, neither more nor less real, than those which show the discontinuity. Results of one kind follow laws which are now familiar to physicists; the others are governed by laws which are not as yet generally recognised. It is to the apparent violations of known laws and not to further confirmation under very precise and specialised conditions that we must look for advances in knowledge. The very rigid limitation of the number of variables, usually imposed upon the experimental conditions, is a most effective barrier to discovery in regions which have not been thoroughly explored. These limitations we have tried—indeed experience has taught us—to avoid.

The *reality* of a J-discontinuity can be established by an observer in an hour's time; the wide generality of the phenomenon has however taken months and even years to establish. The laws which govern it have been studied for thousands of working days and certain general conclusions have been reached. How general these laws are, cannot, of course, be told. But they show with certainty that what have previously been regarded as the fundamental laws of X-ray action are not valid; and they introduce us to entirely new conceptions of X-ray phenomena. It is quite evident that not only is the J-absorption-discontinuity conditional on some unidentified factor but that even the K-absorption edge (discovered by us some twenty-five years ago, and now perhaps too faithfully accepted) is conditional, and not perfectly general. In fact, the whole activity of a radiation in a substance is not governed solely by the wave-length of the radiation and the nature of the substance. Confirmation of this statement will be found in the work of Lindh and others on the absorption of X-rays by light substances—work which showed as alternative results absorption lines and absorption edges. It is such alternative results which we have frequently described in association with the J-phenomenon.

In this laboratory we have observed the disappearance of the K-absorption in a way so pronounced that there is no mistaking it.

It may be that many more years must pass before the results discovered can be attributed to one or two simple measurable quantities. The simplest interpretation has yet to be found. But it is important to know that current theories completely break down—that the quantum (or photon) may become impotent; that an atmosphere of radiation (not independent quanta or harmonic constituents) is effective; that superposed radiations act as a coherent whole; that, so far as the radiation is concerned, something analogous to temperature of radiation is the dominant factor; that the internal state (and history) of a substance (not simply the nature of constituent atoms) determines its behaviour under X-ray action. How far these conclusions apply to the K and L phenomena has yet to be determined, but even *their* conditional nature has been established. Detailed accounts will be published in other journals.

Carbonyls of Lithium, Rubidium and Cæsium

The carbonyls of certain alkali and alkaline earth metals have been prepared previously by the action of carbon monoxide on a solution of the appropriate metal ammoniate in liquid ammonia. In this way, Joannis[1] obtained sodium carbonyl, NaCO, and potassium carbonyl, KCO; Gunz and Mentrel[2] barium carbonyl, Ba(CO)$_2$ and Roederer[3] strontium carbonyl, Sr(CO)$_2$. In the course of researches on the carbonyls proceeding in these laboratories, the corresponding compounds of lithium, rubidium and calcium have been obtained.

The carbonyls were prepared by condensing pure, dry ammonia on to a clean specimen of the metal in question by immersing the containing vessel in a bath at − 60°. After complete dissolution, which occupied about 45 minutes, the excess of ammonia was allowed to evaporate, a gentle stream of pure, dry carbon monoxide being meanwhile passed through the apparatus and continued until the metal ammoniate was wholly transformed into the carbonyl. Because of the highly reactive nature of the metals, ammoniates and carbonyls, all the operations were conducted with the rigid exclusion of both air and moisture.

Lithium carbonyl, LiCO, is a white pulverulent substance quantitatively synthesised by these means: found Li 18·80, 19·62, 21·05 per cent, mean 19·82 per cent; calculated for LiCO, 19·86 per cent. It darkens on standing owing presumably to the liberation of minute amounts of carbon, and, on heating in a vacuum, it begins to decompose at 300° without detonation but with the separation of carbon. At about 500° this change is completed in a short time, the residue consisting of free carbon, carbonate and oxide, the amount of residual carbon indicating that the reaction takes the course,

$$4\text{LiCO} = \text{Li}_2\text{CO}_3 + \text{Li}_2\text{O} + 3\text{C} ;$$

ratio LiCO mol./C atoms, found 1·57, calculated 1·33 (the high ratio being probably due to the loss of carbon in the colloidal form). When treated with water the carbonyl detonated violently, with instant ignition of the gaseous products, a cloud of soot being produced and a residue of carbonate and carbon left. On the other hand, water vapour was absorbed quietly with the formation of a dirty brown liquid. The carbon from the detonation of the carbonyl gave ratios LiCO mol./C atoms lying between 2·5 and 3·5. These results together with those of Joannis, who showed that the gas from the detonation of sodium carbonyl with water contained 86 per cent hydrogen and 14 per cent carbon monoxide, indicate the probability of more than one reaction: the high proportion of hydrogen, together with the presence of carbonate in the residue accords well with a reaction of the type,

$$2\text{LiCO} + \text{H}_2\text{O} = \text{Li}_2\text{CO}_3 + \text{C} + \text{H}_2$$

involving the reduction of water by the carbonyl, which requires LiCO/C = 2.

Rubidium carbonyl is a pure white solid possessing as ordinarily prepared a nacreous lustre and dissolving readily in water to give a pale yellow solution. Quantitative synthesis gave Rb 76·55, 74·89 per cent; mean 75·72 per cent; calculated for RbCO, 75·35 per cent. The lilac colour attributed to some of these carbonyls only appears when the conversion from ammoniate to carbonyl is incomplete, and is undoubtedly due to a fine dispersion of the former material. When rubidium carbonyl is heated in a vacuum, the usual dissociation sets in about 350°, and proceeds with increasing rapidity as the temperature is further raised, carbonate, carbon and oxide being produced.

Calcium carbonyl is a dirty, cream coloured, pulverulent powder: found Ca 40·75, 43·66 per cent; mean 42·21 per cent; calculated for $Ca(CO)_2$, 41·70 per cent. With water, it darkens in colour and partially dissolves with the evolution of heat, but without detonation. When heated in a vacuum it gives carbon, carbonate and oxide, the reaction commencing about 200° and increasing in velocity as the temperature is raised.

Systems of Four Immiscible Liquid Layers

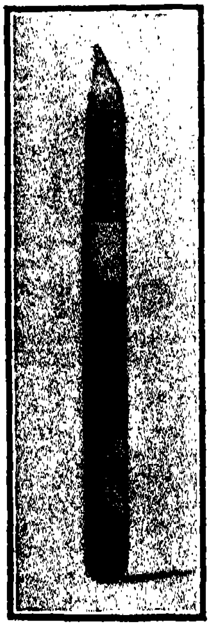

FIG. 1.

IN a recent letter Prof. J. R. Partington[1] states that the system of four immiscible liquid layers described by me[2] does not appear to be stable, inasmuch as a specimen, that originally separated into the four layers, now forms two only. A little more than two years ago I prepared a sealed tube containing this system, plus mercury. It has been shaken repeatedly, but still separates into five layers. Moreover, there has been no noticeable tendency for any one of the layers to decrease in volume, much less to disappear. A recent photograph of this tube is reproduced as Fig. 1. A second specimen, made about the same time, behaved in precisely the same way.

It is difficult to account for the instability of Prof. Partington's specimen, unless indeed impure materials were used (for example, the best oleic acid obtainable commercially is impure) or unless precautions were not taken to exclude atmospheric oxygen and carbon dioxide. The latter will decompose the soap, and the four layers will become three. This might conceivably happen within two years through the action of atmospheric carbon dioxide if the specimens were stoppered with cork or rubber; but then under such conditions the hexane might evaporate away. The suggestion that some decomposition has occurred, or that impure materials were used, is supported by the fact that the two layers of the unstable specimen are reported to be brown in colour.

The phase rule does not demand that systems shall remain in equilibrium in the presence of reactive substances not included among the components. Indeed, it is applicable even when slow interaction between the components occurs. For example, Schreinemakers' studies of the system succinic nitrile, water,[3] and my own of the system sodium oleate, sodium chloride, water, ethyl acetate,[4] are not invalidated because the nitrile and the ester respectively are slowly hydrolysed by the water. These systems would certainly not remain in equilibrium for two years, but as it happens the system under consideration is not of this type. Provided that it is prepared with pure materials and suitably sealed, it seems likely that it will remain unchanged indefinitely, thus constituting the first example of a system of four immiscible liquid layers in permanent true equilibrium. This claim is sufficiently established by the single example illustrated in the accompanying photograph, and is not weakened by the fact that the same phenomena may not be manifested under slightly different conditions.

Vacant Positions in the Iron Lattice of Pyrrhotite

PREVIOUS investigations on the solubility of sulphur in iron sulphide (FeS) have led to the conclusion that the solid solutions of sulphur in iron sulphide are formed by substituting some of the iron atoms in the original lattice by sulphur atoms. Assuming that the radius of the sulphur atoms is smaller than that of the iron atoms, this hypothesis explains the fact that the lattice dimensions decrease with increasing sulphur content. It seems, however, doubtful if this relation between the radii of iron and sulphur atoms agrees with reality, and the difficulties are still more increased when one has to explain the analogous (only more pronounced) lattice variations in solid

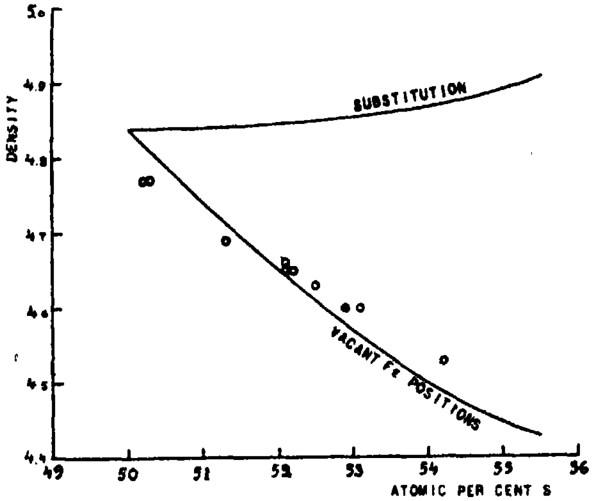

FIG. 1.

solutions of selenium in iron selenide (FeSe) in the same way, on the assumption that the selenium atoms are smaller than the iron atoms.

There exists, however, a second explanation of the observed effect, which requires no special relation between the sizes of the two kinds of atoms, namely, that the excess of sulphur is caused by an increasing number of vacant positions in the iron lattice. Recent X-ray measurements carried out in this Institute show that the phase of the 'nickel arsenide type', constituting the solid solutions in question, is homogeneous from about 50 to about 55·5 atomic per cent sulphur, and by means of the lattice dimensions observed, the density has been calculated for a solid solution of the substitution type and for the type characterised by vacant iron positions. The curves are shown in Fig. 1 together with previously observed density values, which strongly favour the assumption of such vacant positions.

Theoretically, it should be possible to decide the question also by intensity measurements of the X-ray interferences, but in this case the difference necessitated by the two theories is too small to be detected. A study of the solutions of selenium in iron selenide, where the difference should be more marked, and also where the density measurements probably will give a still more striking difference, has been begun.

No definite facts indicate a regular distribution of the vacant positions, so possibly they might be distributed at random in the iron lattice. Theoretically, the appearance of random vacancies is as natural as the appearance of random substitution, or of a random adding of dissolved atoms into the interstices of a lattice. These vacant positions make a new type of solid solution like the above possible, and the possibility of their appearing should be kept in mind in the determination of any structure where they are not electrostatically impossible.

In this connexion it might be mentioned that the present study has shown that the phase under investigation exhibits a 'superstructure' at the homogeneity limit richest in iron, that is, at the composition FeS. The symmetry is still hexagonal, but the longest basal diagonal of the old unit cell (of the nickel arsenide type) becomes the *a*-axis in the super cell, while the *c*-axis of the old cell is doubled. The new super cell contains 12 iron and 12 sulphur atoms. The superstructure disappears rapidly when the sulphur content of the phase increases.

Positive Ion Emission from Oxide Catalysts

It was shown recently in this laboratory[1] that the emission of positive ions from a heated Kunsman catalyst is accompanied by the evaporation of neutral atoms. In particular, a cæsium source heated in the neighbourhood of a sodium source deposited cæsium on the latter, so that when it was heated in turn, it emitted cæsium and not sodium ions. The number of cæsium ions emitted from the sodium source was large in this sense that it corresponded to the deposition on the superficial area of the source of a layer of cæsium a thousand atoms thick.

Cæsium atoms evaporate uncharged from cæsium in bulk and a layer more than two or three atoms thick must behave in the same way. Thus we find that cæsium deposited in varying thicknesses on a tungsten surface, which is then heated, always results in the emission of the same quantity of positive charge. This charge corresponds to the emission of the last layer of the cæsium on the tungsten, which is held to the surface as ions, the overlying atoms being evaporated in the neutral state. In the experiments with the oxide sources, the cæsium must therefore have been distributed on the surface of the microcrystals throughout the source. At temperatures below that at which the cæsium evaporates appreciably, the cæsium atoms must be able to migrate over the crystal surfaces, possibly in the way suggested by Lennard-Jones[2], so that the deposition results in a large surface being covered by a monatomic layer of cæsium ions.

This result suggested that it might be possible to produce positive ion sources of other metals by evaporation on to an iron oxide base, and experiments were made with thallium, indium and gallium. With thallium and indium we obtained very pure sources of the corresponding ions which gave an emission of 20 microamp. per sq. cm. for many hours. With gallium the results were unsatisfactory and the sources soon failed. The ions were identified by mobility measurements in pure nitrogen. In this gas we have found that the determination of the mobility of a positive ion gives an unambiguous measure of its mass[3].

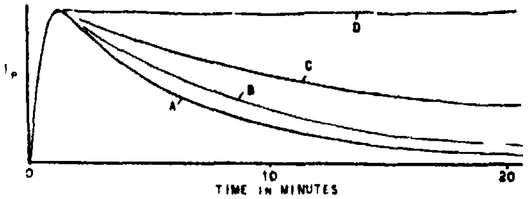

Fig. 1.

To investigate this difference between the different metals, we made experiments in which a known amount of metal could be deposited on the oxide base. After the deposition, the oxide was heated to a given temperature and the resultant positive ion emission measured. In Fig. 1, this emission, i_p, is plotted against the time. Curves *A*, *B*, *C*, *D* are for progressively increasing amounts of deposited thallium. The results showed that a very large proportion, probably 100 per cent, of the deposited metal was re-emitted as ions when the source was heated. Secondly, in all the curves it will be seen that the initial maximum current is the same. This maximum current is the emission, at the given temperature, characteristic of the surface when saturated with positive ions. At the beginning of the heating of the source, the outer surface is fully saturated. Unless it can be maintained in this state by the migration of ions from the interior, the emission falls off. The possibility of maintaining the outer surface in the saturated condition must depend upon the concentration of ions on the crystal surfaces in the neighbourhood of the outer surface. With large depositions these are saturated and the emission remains constant (see Fig. 1, curve *D*).

If for a given metal the emission characteristic of the saturated surface is measured at increasing temperatures, it is found to rise rapidly like the saturated electronic emission from a heated filament. From this curve an approximate value of the positive ion work function can be found. At a certain limiting temperature the iron oxide sinters and the emission falls and becomes unstable. This temperature limitation defines the maximum emission that can be taken from an iron oxide source with a given metal on it. The higher the work function for the positive ions the lower the maximum current. In the mobility experiments with gallium we must have exceeded this limiting temperature in the attempt to obtain the necessary emission.

Details of these experiments, together with others on the properties of surface ionic layers of other metals on various oxides, will be discussed in another place. We may point out here the significance of these results in connexion with the catalytic action of the Kunsman source in the production of ammonia which we have found to take place at low pressures[3] and which is used as an industrial process. The catalytic activity may be assumed to be directly associated with the presence of alkali ions on an enormous area, and any activity of the oxide in the absence of added alkali to the inevitable presence of traces of the alkalis as impurity, for a small mass of alkali will cover a large area as a monatomic film.

Fusion of Carbon

IN the course of an investigation on the behaviour of the carbon arc in various gases at high pressure, carried out in apparatus provided by Imperial Chemical Industries Ltd., we have obtained large amounts of carbon in a fine state of division. In certain circumstances this carbon is deposited as graphite, all in the form of small spherules of about 0·02 mm. diameter or smaller, having a density 2·25. There seems to be little doubt that these spherules of graphite have been formed owing to the effect of surface tension, the carbon having persisted for a finite time in the molten state. The best yield was obtained at 90 atmospheres in hydrogen with an arc dissipating 20 kilowatts. The temperature of the positive crater at this pressure has not yet been determined. The surface brightness at 10·5 atmospheres was 2·18 times that of the arc at atmospheric pressure for the same wave-length, corresponding to an increase of brightness temperature of 460°. The increase in the thermodynamic temperature must be of the same order, so that the temperature was probably much higher at 90 atmospheres. Further investigations are necessary before the precise conditions under which the spherules are formed are established. The percentage of ash left after burning the carbon of the electrodes was 0·8, that from the carbon collected from the arc chamber less than 3 per cent. It is scarcely likely that this amount of fusible ash could cause the whole of the carbon to adopt spherical form.

Braun[1] has mentioned the formation of microscopic spheres of carbon from thin carbon filaments through which the discharge from a number of Leyden jars was passed, while Lummer's investigations on the peculiar molten appearance of the positive crater in arcs at low pressure described in his book on the "Verflussigung der Kohle" are well known, but no evidence of the melting of carbon is quite so convincing as the appearance of these graphite spherules, obtained in the above manner.

Liesegang Rings

IN reply to Dr. Bradford's letter[1] I would say that the more comprehensive a theory is, the more general and apparently indefinite must be the terms in which it is expressed. If for my indefinite term 'mobilisation' is substituted the more definite term 'adsorption', my theory of periodic structures becomes almost identical with Dr. Bradford's. But I believe that adsorption is only one of the means by which the substance may migrate towards the structure already formed, and I prefer, therefore, to use the less definite term 'mobilisation' to include all these means.

It is not correct to suppose that in accordance with my theory all systems should give periodic structures, for the critical conditions postulated may be absent or only slightly developed. Nevertheless, it is probable that a system not usually given to periodic structure formation can always be made to furnish periodic structures by alteration of these conditions. This, I believe, is a point also upheld by Dr. Bradford.

Nitrogen Fixation in the Genus *Lolium*

THE results of some recent experiments suggest that it is highly probable that part of the nitrogen requirement of plants of the genus *Lolium* is met from atmospheric sources.

Experiments were designed to test the effect of withholding atmospheric nitrogen from the plants. The plants were grown in sterile silver sand, which had previously been freed of all traces of nitrogen. The containers for the sand were large specimen tubes. There were two separate series of these sand cultures, one supplied with combined nitrate nitrogen, the other without it. Two sterilised seeds were buried in each tube, four tubes of each type were placed under a bell jar which was made gas-tight, and a mixture of 80 per cent hydrogen, 20 per cent oxygen and 0·03 per cent carbon dioxide was drawn through. A control series of the same types and prepared under the same experimental conditions was run simultaneously under a bell jar through which atmospheric air was drawn. During these early experiments the gas mixture of both chambers was drawn through the sand. The gas in the chambers was changed once every twenty-four hours. The hydrogen and oxygen were prepared electrolytically, and the carbon dioxide by the action of hydrochloric acid on marble chips.

The experiment was kept going for seven weeks.

At the end of that time the plants in the air chamber were markedly healthier and bigger than those in the hydrogen chamber.

A similar experiment was afterwards set up, observing the same precautions, but it was modified to yield quantitative data and to give some indication of the effect of hydrogen on the growth of the plant. Bell jars as gas chambers sufficiently large to cover forty tubes were used. A third chamber was added, through which a gas mixture of, in percentage proportions, hydrogen 40, nitrogen 40, oxygen 20, and carbon dioxide 0·03, was drawn. This experiment was kept going for eight weeks, and at the end of that period the lengths of all the leaves and the dry weights on each plant were determined. The lengths of the leaves were measured as indices of area; the small width of the leaves rendered the direct determination of this quantity extremely difficult. The mean total leaf length in centimetres and the mean dry weight in grams per plant are presented in the accompanying table.

Gas Mixture	Culture Solution		
Nitrogen, oxygen and carbon dioxide	+ Nitrate	Leaf length Dry weight	26·4 0·0018 (1)
	– Nitrate	Leaf length Dry weight	21·5 0·00148 (2)
Nitrogen, hydrogen, oxygen and carbon dioxide	+ Nitrate	Leaf length Dry weight	36 0·00322 (3)
	– Nitrate	Leaf length Dry weight	23·1 0·00164 (4)
Hydrogen, oxygen and carbon dioxide	+ Nitrate	Leaf length Dry weight	27·2 0·00228 (5)
	– Nitrate	Leaf length Dry weight	18 0·00136 (6)

The difference between the dry weights of (2) and (6) is only slightly greater than the standard error of the difference of these means, but the difference in leaf lengths is more than twice the standard error of the difference of the means. The latter difference is, therefore, probably significant. The best growth was that made in the gas mixture containing both nitrogen and hydrogen. The stimulating effect of hydrogen under the conditions of the experiment is also evident from series (5) when compared against series (1). The conclusions would therefore seem to be justifiable that the stimulating effect of hydrogen is masking the depressant effect of absence of nitrogen in (5) and (6).

Ambiguity in Sign of Spearman's General Factor

IN a previous letter,[1] I gave a sketch of a method for obtaining an explicit formula for the general factor g and the specific factors which occur in Spearman's two-factor theory of intelligence. By developing this method, I obtain the following results.

If the tetrad relations hold, the factors exist. If two more conditions hold, the factors are real. If a fourth condition holds, they are unique except in sign. In the case which occurs most often in actual experiment, when all the coefficients of correlation between the tests are positive, the value of the general factor with one sign seems to correspond to something like general ability and the value with the other sign to the lack of that ability. But in other cases, when some of the coefficients of correlation are negative, it is not clear how to distinguish between the interpretations of the two possible values of the general factor.

After a discussion of the effects of pooling tests, the results have been applied to a dice problem, and to actual sets of mental tests. It is found that both for the dice throws and for the mental tests, the general factor exists and is real, but is not unique, even in numerical value. The comparison between dice throws and mental tests, when examined closely, breaks down in one important respect. Finally, the possibility is examined of making the numerical value of the general factor approximately unique, by making the ratio of the standard deviations of the indeterminate and determinate parts a given small fraction. I have shown that to do this by merely multiplying the number of tests is quite impracticable; the only method available is to choose one or more tests that correlate very highly indeed with g. In the case of Kelley's tests, it is found that the fraction which we wish to make small appears to be 0·09, but that this value is very doubtful on account of the tetrad relations not being satisfied exactly. The use of figures corrected for attenuation leads to the conclusion that either some of the factors are imaginary, or, what is more probable, that the correction for attenuation is not reliable.

A full account of this work will be offered to a psychological journal in the near future.

Spectra of Bromine: Br V, VII and IV

IN continuation of our previous work on the spectra of arsenic and selenium, the spectrum of bromine has been investigated by a study of photographs taken under different conditions of excitation. The chief multiplets belonging to the higher spark spectra of bromine have been easily identified. The characteristic intervals of the deepest ^3P terms in Br V and Br VII have been found to be 6090 cm.$^{-1}$ and 7580 cm.$^{-1}$ respectively, while $4p\ ^3P_0 - 4p\ ^3P_1$ and $4p\ ^3P_1 - 4p\ ^3P_2$ of Br V are 2115 and 4906 units.

A full report of the analysis will be published shortly.

The experimental data referred to above have led one of us (A.S.R.) further to the identification of many of the chief groups of Br IV arising from the transition of the electron from the $4p$ to the $5s$, $4d$ and sp^3 states. The intervals of $5s\ ^3P_{0,1,2}$ are found to be 1281 cm.$^{-1}$ and 4688 cm.$^{-1}$. This classification does not agree with the scheme suggested by S. C. Deb[1], which the writer thinks is out of step in the iso-electronic sequence Ge I to Br IV.

Research Items

Hawaiian Feather Cape. In *Man* for January Mr. H. G. Beasley figures in colour and describes a feather-cape from Hawaii, which he acquired for the Cranmore Ethnographical Museum, Chislehurst, in 1932. The cape measures 62 in. round the base and is 25 in. in depth, thus falling into the intermediate series, in which the base-line measurement is that of a full-sized cloak, but the shallow depth that of a cape. The ground-work is of red Iiwi feathers (*Vestiaria coccinea*) and the pattern and border are of yellow Oo (*Acrulocercus nobilis*). The main body of the foundation is somewhat coarse; but the six-inch border is of finer meshed work. The cloak belonged to Sir Joseph Banks and was given by him to his private secretary, Mr. R. K. S. Durham, from whose grandson it was obtained by Mr. Beasley. It is to be presumed that Banks obtained the cloak from one of the officers who sailed with Cook in his later voyages; but the connexion with any one of Cook's voyages cannot be established. In a supplementary note Mr. H. J. Braunholtz adds that the birds from which the feathers were taken were captured alive and often released after they had been plucked. The popular belief that the Oo bird had only two yellow feathers is erroneous: actually the yellow feathers form axilliary tufts containing 15–20 feathers. The feathers are attached to a net of fibre, each separately, by a finer thread of the same material. The use of cotton thread is a sign of modernity. The British Museum now has twenty-six of these feather capes or cloaks, presumably the largest collection in existence. They were first described by Capt. King in his account of Cook's third voyage when the Hawaiian group was discovered in January 1778.

Gods of Maya and Aztec. In an appendix to a study of the calculations of the solar year in Mayan inscriptions on stone stelæ at Quirigua, Guatemala (Field Museum of Natural History, Chicago, Pub. 315, Anthropological Series, vol. 17, No. 4), Mr. J. Eric Thompson considers how far any resemblance may be detected between the Aztec 'Lords of the Night' and the equivalent Maya glyphs of the gods. The sun god is unmistakable. Xiuhtecutli, the fire god of the Aztec, is the Maya glyph in which a flame bracket branches from the god's mouth. In one instance, three balls of flame are shown above the head. Itzli, the second in the Aztec series, has no known Mayan equivalent. Piltzintecutli, the Aztec sun god, in the Maya series is Kinich Ahau, both being associated with a flower or leaves. The fourth Aztec god Centeotl is the maize god, corresponding to the Maya glyph showing a head with the numerical co-efficient of nine and a large human hand, which, the evidence goes to show, denotes an agricultural deity. Mictlantecutli, the Aztec death god, is represented by the Maya glyph with the coefficient of three. Only two examples of the glyph are known and the connexion with death is not clear. The Mayan equivalent for the sixth Aztec 'Lord of the Night', Chalchihuitlicue, goddess of water, through the month sign Mol and day sign Muluc, may also be connected with water. One of the closest parallels is that between Tlazolteotl, the Aztec earth goddess and the Mayan moon goddess, wife of the sun. Both are connected with agriculture, the Aztec through maize, the Mayan through flowers, and both are also concerned with sexual indulgence. The eighth Aztec god, Tepeyollotl, is an obscure earth and mountain deity, who as a jaguar-like animal has a conch shell as symbol. This connects him with a Mayan mountain deity. The ninth and last in the Aztec series is Tlaloc, the rain god. The equivalent Mayan glyph is a young deity with an ear-flap, of which only two examples are known. The association is not clear. Thus in six out of the nine, a remarkable coincidence between Aztec and Maya is apparent.

Making Whole Mounts of Vertebrate Skeletons. Mr. M. Rahimullah and Prof. B. K. Das, of Osmania University College, Hyderabad, have sent a communication describing a method of preparing the whole skeleton, free from soft parts, of a vertebrate, such as a snake or a rat, by a modification of the well known alizarin and caustic potash method. The chloroformed animal is fixed and hardened in strong alcohol (about 92 per cent) for four days, then rinsed in tap water and transferred to a 1 per cent solution of caustic potash. After a period of at least eight days, the bones can be seen through the translucent skin and muscles. The animal is then transferred to a solution of alizarin and caustic potash (made by dissolving 0·1 gm. or less of alizarin *S* in 1,000 c.c. of 1 per cent potash), where it remains for at least twelve days, until the bones take a deep pink hue. The macerated muscles are then dissected away, leaving the skeleton intact. It is not clear from the communication whether the connective tissues uniting the bones have escaped maceration, or whether the articulation of the parts of the skeleton remains to be done in the usual way, but the former claim seems to be made. The hairs of mammals remain opaque, but after a few days in the potash solution they are loose enough to be scraped away with a section lifter or similar instrument. In this way albino rats and young rabbits have been successfully treated.

Early Stages of Hispine Beetles. While there remains still very much to be done in the morphological and anatomical studies of insects in the adult stage, this work is progressing much more rapidly than the study of their immature stages. Researches in the morphology of the latter, however, can be of great interest and value since a number of general biological problems are suggested by them. This is shown very clearly by recent detailed work of S. A. Maulik on the larval and pupal structures in the beetles of the subfamily Hispinæ (*Proc. Zool. Soc. Lond.*, 1932). These larvæ live in tunnels inside leaves and their morphology presents numerous cases of remarkable specialisation due to this mode of life. Thus, the legs show a complete gradation from a well-developed condition to one of great degeneracy, where the claws disappear altogether. The position of the spiracles presents various significant modifications in the larvæ, while their number also varies with the species. In one case the number of larval spiracles was found to vary even within the species and, moreover, there appeared to be a correlation between the number of spiracles in the larva, and the colour pattern of the adult beetle. Some observations point to the possibility of two or more species of the same genus living together in the same tunnel, and this may lead to interbreeding and hybridisation, which would supply a hypothetical explanation of the great variety of colour-patterns in the adults.

Growth of Corals. T. Tamura and Y. Hada record observations (*Science Reports*, Tôhuku Imp. Univ., vol. 7, No. 3, 1932) on the growth of corals in the Caroline and the Pelew Islands respectively. They found that the average annual growth in *Acropora pulchra* was 226 mm. and in *A. digitifera* 12 mm.; the former has a light skeleton, the latter a dense and heavy one. Massive corals, for example, *Porites, Montipora, Favia*, showed an average annual increase in length of about 6 mm., and in weight of about 33 per cent. *Fungia* showed an increase in length of about 9 mm. and in weight 23 per cent. The rate of growth in both localities is similar to that recorded for Hawaiian corals. Each species has a characteristic growth rate; after a specimen reaches a certain size growth ceases. In the preceding paper in the same journal, Y. Hada gives an account of the early stages of growth of *Pocillopora cespitosa*, the planulæ of which are extruded probably throughout the year but most actively during December. The youngest colony found was 1·5 mm. in diameter and consisted of three polyps. The next period of growth results in lateral spreading of the colony until about thirty polyps have been formed; then the colony begins to grow vertically and to branch. The number of polyps now increases about three times as fast as in colonies which are still undergoing lateral extension.

Some Noteworthy Irish Plants. Dr. Lloyd Praeger's paper (*Proc. Roy. Irish Acad.*, 41, Sec. B, No. 7, Dec. 1932) contains much of interest to students of topographical botany, whilst his account of the genus *Cochlearia* in Ireland will be of value to British botanists as ecological observations on the species and notes on hybrids of *C. officinalis* with *anglica, danica* and *grœnlandica*, are given. A revised distribution of these species in Ireland is given, the previous confusion with regard to *C. anglica* being attributed to the frequency with which it hybridises with *C. officinalis*. Investigations on the distribution and associates of *Arbutus* at Lough Gill lead to the conclusion that the plant is native in Sligo, thus extending by 160 miles its northernmost Irish and European limit. The occurrence of *Arctostaphylos alpina* in Ireland and the record of *Euphorbia hiberna* from Roscommon are discredited, whilst the status of *Tamus* as an indigenous plant is re-examined, the author inclining to regard it as native in Sligo. *Polypodium Robertianum* is established as a native species new to Ireland whilst many new stations are given for the hybrid *Equisetum litorale*, and *Scrophularia alata* is recorded from Limerick and Londonderry. Other notes deal with introduced species including *Sarracenia purpurea* from Roscommon and Westmeath, *Erica stricta* from Antrim and Londonderry and an unconfirmed record of *Selaginella Kraussiana* from Donegal.

The Ankole Tinfield. Memoir No. II of the Geological Survey of Uganda is devoted to "The Geology of South-west Ankole and Adjacent Territories, with Special Reference to the Tin Deposits". Apart from an appendix on the petrology of the rocks of the region contributed by A. W. Groves, and a postscript by W. C. Simmons, the memoir is the work of A. D. Combe. It contains a well-illustrated, authoritative account of the geology of south-west Uganda and north-west Tanganyika based on ten years' detailed field work. Cassiterite is the only mineral of economic value that occurs in workable quantities in this area, and though production did not begin until 1927, more than a thousand tons have so far been exported. The mineral occurs in quartz-muscovite-pegmatites and in hydrothermal veins associated with them, veins of hydrous micas and muscovite having proved to be the most important producers to date. All the veins are found in the metamorphosed rocks of the Karagwe-Ankolean system adjacent to the margins of various masses of the so-called Younger Granite. Much of the muscovite with which the tin is associated is thought to have been produced by metasomatic alteration of the phyllites. Combe and Simmons suggest that the alkaline liquors responsible for this alteration also acted as carriers for the tin, but Groves believes that fluorine was probably an active agent in the introduction of tin, despite the absence of topaz. This opinion has also been expressed by Stheeman in a recent book on the same area. The memoir contains a wealth of information on one of the most interesting parts of Uganda and is of importance to stratigraphers because of the attention given to the Karagwe-Ankolean formations and their distribution and correlation, as well as to geologists in general because of the wide range of problems that come under discussion. The memoir is obtainable from the Government Printer, Entebbe, Uganda, price 35*s*.

Meteoric Craters. In a paper to the Royal Geographical Society on January 16, Dr. L. J. Spencer discussed the origins of meteoric craters such as that in Arizona, those in Central Australia and in Estonia or the one recently discovered by Mr. H. St. J. Philby on the site of Wabar in the Arabian desert and described by him in the *Geographical Journal* for January 1933. Little is known about the mode of formation of these craters but the suggestion that they are merely holes formed by the projectile force of the meteor is not an adequate explanation. Meteorites of which the fall has been observed have all been small and their velocity, reduced by resistance of the air, has been about seventy metres a second. They have never penetrated far into the ground. The largest discovered meteorites, the fall of which has not been noted, have not formed craters but lie either on the surface or with their tops flush with the surface. Dr. Spencer suggests that meteoric craters are formed by explosions due to the sudden vaporisation of part of the material both of the meteorite and the surface of the earth as a result of the intense heat generated by the impact. He showed how the destruction of material within the crater agrees with this theory, which also explains the formation of silica-glass found in association with the crater (see also NATURE, Jan. 28, p. 117).

Physical Atomic Weights. In the Liversidge lecture to the Chemical Society (*J. Chem. Soc.*, December 1932), Dr. F. W. Aston described some recent results obtained with the mass-spectrograph. In the case of elements which are mixtures of isotopes, a measurement of the relative intensities of the lines in the mass-spectrogram will lead to an average atomic weight of the element which may be compared with the chemical value. This operation is, however, experimentally very difficult, owing to the circumstances that the source of the positive rays is never reproducible and seldom constant for more than a very short time and also that the relation between relative abundance of isotopes and blackening of the plate is completely different for different elements. Dr. Aston described the experimental procedure adopted in overcoming these difficulties. The results, based on $O^{16} = 16$, require correction by 2 in 10,000 to reduce them to the chemical scale, O = 16, since ordinary oxygen contains the isotopes O^{17} and O^{18}, and a comparison of the two sets of values shows that the agreement is in the great majority of cases exceedingly satisfactory. There is a discrepancy in the case of hydrogen, which cannot be removed by the recent discovery of an isotope of mass number 2, which is present only to the extent of 1 part in 35,000. Scandium, niobium and tantalum, which are simple elements, show discrepancies, their chemical atomic weights being too high, and the same is true, to a less degree, of phosphorus and cæsium. The serious difference in the case of selenium has been removed by Hönigschmid, whose chemical value is identical with the physical one. The physical value for tellurium, which differed from the chemical one, has been corrected by Bainbridge, whose result agrees with the chemical one. The values for osmium and uranium are also abnormal.

Simple Molecules and Elementary Processes. Two lectures by Prof. A. J. Allmand on the above subject have been published by the Institute of Chemistry, and form a very clear and concise introduction to a field of research which has recently been actively studied. In the first lecture the experiments of Stern and his collaborators on molecular rays are briefly considered, and then an account is given of molecular spectra, the text here being illustrated by several useful diagrams. The parts played by the electronic, vibrational and rotational energies of the molecule in producing the spectra are clearly explained, and the importance of Raman spectra in deciding the natural frequency is emphasised. The second lecture dealt with a miscellaneous group of phenomena giving information about the mechanism of individual chemical molecular processes. The evidence for the existence of free radicals such as OH, NH, CH, etc., from spectroscopic results is considered in connexion with the energy of linkage. The chemical reactions of atomic hydrogen and atomic oxygen, the chemical evidence for the existence of free radicals given in the experiments of Paneth and F. O. Rice, chain reactions, predissociation, and three body collisions are topics dealt with in this lecture. Prof. Allmand's lectures will be found to constitute an admirable introductory survey of a highly interesting field of modern physical chemistry.

Astronomical Topics

Comet Peltier-Whipple. This was probably the brightest of the numerous comets that were observed in 1932. It was on the verge of naked-eye visibility at the end of August. *Astr. Nach.*, 5905, contains observations of it made by R. M. Aller of Lalin Observatory on twelve nights between August 25 and September 19; also drawings of the comet on August 27, 28, September 2 and 7. The tail is multiple; the main branch is triple and was traced to the length of a degree on August 28. Its position angle changed from about 300° on August 27 to about 330° on September 7. A short, but bright, tail was inclined at about 45° to the main tail, on the side of greater angle. The sketches show a coma about 3′ in diameter round the nucleus.

Mr. H. Jensen of Copenhagen finds 287·2 years as the period, and Mr. F. Koebcke of Poznan 286·8 years (Copenhagen Circulars 403, 404). Search in the catalogues does not show any previous apparition of the comet.

A determination of the light-curve of the comet has been published by K. Himpel (*Astr. Nach.*, 5913). It was of magnitude 6·7 on August 12, and slowly rose to a maximum of 6·3 on August 24: it then declined rapidly, being 7·7 on September 9. A very thorough investigation of its orbit, by Dr. Allan D. Maxwell (Publ. Univ. Michigan, vol. 5, No. 2) gives the period as 302·5 years. Comparison with other determinations suggests that this is unlikely to be more than some ten years in error.

Galactic Rotation. *Lick Observatory Bulletin* No. 448 contains an investigation on this subject by Miss Phyllis Hayford. It is necessary for this purpose to observe the radial velocities of distant objects. This investigation made use of a large number of spectrograms of stars in the Milky Way clusters, obtained with the 36-inch refractor; Dr. Trumpler took many of the plates, but all were measured by Miss Hayford. The clusters are all within 10° of the galactic plane, and are distributed fairly uniformly from galactic longitude 311° through 0° to 206°. 116 of the stars are of type *O5* to *B5*, 32 of type *B6* to *A2*, and 13 of later type. Their magnitudes range from 5·3 to 12·2; their adopted distances range from 940 to 3,680 parsecs.

As is to be expected, the solar motion relatively to these distant stars is higher than that derived from neighbouring stars; it is about 30 km./sec. The longitude of the galactic centre, 333°, agrees well with other determinations. The investigation confirmed the result of Dr. Plaskett and others that the interstellar calcium lines indicate a smaller distance than that of the stars in the spectra of which they are measured.

The distance of the galactic centre is found to be of the order of 1,800 parsecs from the sun, a much smaller distance than that found by Dr. Oort, which was about 6,000 parsecs. But the new distance, being derived from a limited number of objects, does not claim to be final.

Mutual Eclipses and Occultations of Jupiter's Satellites. Every six years the system of Jupiter is turned edgewise to us; at such times, numerous eclipses and occultations of one satellite by another take place. Until recently these phenomena were unpredicted, and in consequence they were very seldom observed. The Computing Section of the British Astronomical Association now makes predictions which are published in the B.A.A. Handbook; very many have been observed during the past twelve months. *L'Astronomie* for September contains an illustrated account of the occultation of IV by I observed by M. Schlumberger at Mulhouse on March 14, 1932; the occultation was very nearly total. The surface of IV is so much darker than that of I that it is easy to distinguish the two bodies when the discs are overlapping; at the maximum phase a very narrow segment of IV remains uncovered.

Prize Awards of the Paris Academy of Sciences

At the annual public meeting of the Paris Academy of Sciences, held on December 12, the prizes and grants for 1932 were awarded as follows:

Mathematics.—The Poncelet prize to Raoul Bricard, for his work in geometry; the Francœur prize to Henri Milloux, for his work on analytical functions.

Mechanics.—A Montyon prize to Jules Haag, for his work on chronometry; the Fourneyron prize to Maurice Roy for his work in applied mechanics; the Henri de Parville prize to Joseph Pérès, for his work in hydrodynamics; the Henry foundation to Dimitri Riabouchinsky for his work in aerodynamics and hydraulics.

Astronomy.—The Lalande prize to Abel Pourteau for his studies on the statistics of the double stars; the Damoiseau prize to Nicolas Stoyko for his studies on the measurement of time and allied problems; the Benjamin Valz prize to Jean Dufay for his work in astronomical photometry; the Janssen medal to Alexandre Dauvillier for his studies on the aurora polaris and allied phenomena; the La Caille prize to Eugène Antoniadi for his work on planets.

Geography.—The Delalande-Guérineau prize to Ernest Benoit for his theoretical works and geodesic operations in the field; the Gay prize to Emile Hasse for his calculations and discussions of geodesic and astronomical work carried out by the geographical service of the army; the Tchihatchef prize to Mme. Tardieu for her memoir on the ferns of Tonkin; the Binoux prize to the late Jules Hansen for his map of "L'Ancien Pays de Luxembourg".

Navigation.—The Navy prize to Pierre Malaval for his work on the resistance of materials; the Plumey prize to Henri de Leiris for his memoir entitled: "Experimental Researches on the Fatigue and Expansion of Steam Pipes".

Physics.—The L. La Caze prize to Eugène Darmois for the whole of his work; the Hébert prize to Charles Lavanchy for his work on the calculation and construction of high tension aerial cables; the Hughes prize to Emile Henriot for the whole of his work, especially on the radioactivity of the alkaline metals, the double refraction of compressed glass, high angular velocity cathode and magneto-cathode rays: the Clément Félix foundation to Gaston Dupouy for assisting his researches on magnetism.

Chemistry.—A Montyon prize (unhealthy trades) to Eugène Burlot for his work dealing with the safe handling of explosives and compressed gases; Raymond Horclois received a mention (1,500 francs) for his researches on the application of negative catalysis for extinguishing fires; the Jecker prize to the late Marc Bridel for his work in biological chemistry; the L. La Caze prize to Louis Hackspill for his researches in inorganic chemistry; the Cahours foundation between Paul Thomas and Paul de Graeve for work on fermentation; the Houzeau prize to Dimitri Ivanoff for his work on Grignard syntheses.

Mineralogy and *Geology.*—The Fontannes prize to Gustave Sayn for his palæontological work; the Victor Raulin prize to Louis Royer for his crystallographic work; the Demolombe prize to Paul Bertrand for his work in palæobotany.

Botany.—The Desmazières prize to René Morquer for his work entitled: "Morphogenic Researches on *Dactylium macrosporum*"; the Montagne prize to Gontran Hamel for his work entitled: "*Chlorophyceæ* of the French Coasts"; the de Coincy prize between Alfred Saint-Yves and the late John Briquet.

Anatomy and *Zoology.*—The Cuvier prize to Pierre Fauvel for his researches on annelids; the Savigny prize to Armand Billard for his work on the hydroids of the Bay of Suez; the Thore prize to Pierre de Boissezon for his memoir entitled: "Contribution to the Study of the Biology and Histophysiology of *Culex pipiens*".

Medicine and *Surgery.*—Montyon prizes to Paul Chevallier for his work on Hodgkin's disease, Philippe Lasseur and Mlle. Andrée Dupaix for their microbiological work, Victor Veau and Mme. Suzanne Borel for their work on palatal division; honourable mentions to Jean Albert Weil for his book on the poisons of the tubercle bacillus, to Grégoire Ichok for his book on work for the sick and infirm, and to Raoul Leroy and Georges Médakovitch for their book on general paralysis and malaria therapy; citations to Henry Chabanier and Carlos Lobo-Onell for their book on diabetes and to Charles Dubois and Noël Sollier; the Barbier prize to Stefan Jellinek for his researches on apparent death produced by electric shock; the Bréant prize (in equal parts) between Pierre Delanöe for his studies on the Moroccan spirochæte and Jean Sabrazès, Georges Jeanneney and René Mathey-Cornat for their book on bone tumours; the Godard prize to Mlle. Marthe Lamy for her book on gonococcic coxitis; the Mège prize to Henri Bouquet for his illustrated encyclopædia of medical knowledge; the Bellion prize to Edouard Imbeaux for his statistical and descriptive annual of the distribution of water and drainage in France, Algeria, Tunis, Morocco and French Colonies, Belgium, Switzerland and Luxembourg; the Baron Larrey prize to Jules Beyne, for his studies in aviators' sickness.

Physiology.—The Montyon prize to Henri Fredericq for his researches on the nerve control of the heart; the L. La Caze prize to Emile Abelous for his work in physiology, especially chemical physiology; the Pourat prize to Louis Rapkine for his work on the energetics of development, oxido-reduction potentials in cells and the chemical processes in the course of cell division; an honourable mention to Gabriel Laniez; the Martin-Damourette prize to Paul Fleuret for his work on the nutrition of animals; the Philipeaux prize to Paul Kucharski for his researches on audition.

History and Philosophy of Sciences.—The Binoux prize to Abel Rey, for the whole of his work on the history of science.

Works of Science.—The Henri de Parville prize between Jules Rouch, for his work on oceanography, meteorology and polar expeditions, and Georges Kimpflin, for his publications on artificial resin and the problem of heating.

Medals.—The Berthelot medal to Eugène Burlot and to Louis Hackspill.

General Prizes.—The prize founded by the State to Jacques Soula for the whole of his work; the Alhumbert prize to Francis Myard for his work on articulated systems; the Bordin prize to Gabriel Arnaud and Mme. Madeleine Arnaud for their treatise on plant pathology; the Lallemand prize to François Kiss and Jules Botár for their work on the physiology of the nervous system; the Serres Prize to Edouard Chatton for his work on the evolutive cycle and the determinism of sexuality in the Protozoa; the Vaillant prize to Maurice Gevrey for the whole of his work on partial differential equations; the Houllevigue prize to Albert Policard for his work in histophysiology and histochemistry; the Saintour prize to Albert Vandel for his work in zoology and general biology; the Lonchampt prize to Étienne Canals for his study on the physiological rôle of magnesium on plants; the Wilde prize to Ernest Chaput for his geological work; the Caméré prize to André Coyne for his work in civil engineering; the Gustave Roux prize to Pierre Bonnet for his thesis on sloughing, autotomy and regeneration in spiders with a study of the European Dolomedes; the Thorlet prize to Adolphe Richard; the Albert I of Monaco prize to Louis de Broglie for his researches in wave mechanics.

Special Foundations.—The Lannelongue foundation between Mmes. Cusco and Raphaël Rück; the Hélène Helbronner-Fould prize to Mme. Gustave Ferrié.

Prizes of the Grand Ecoles.—The Laplace prize to Jacques Desrousseaux; the L. E. Rivot prize between Jacques Desrousseaux, Georges Périneau, Jean Crussard and Jacques Aubriot.

Foundations for Scientific Research.—The Trémont foundation to Lucien Malassis for his inventions and work in connexion with calculating machines; the Gegner foundation to Wladimir Margoulis for his work in nomography with applications to aerodynamics and aviation; the Jérôme Ponti foundation to Jean Orcel for his work in metallography and opaque minerals; the Hirn foundation to Adolphe Buhl for his studies on the transformations and invariances of multiple integrals; the Henri Becquerel foundation to Henri Galbrun for his work on the calculus of probabilities and other mathematical researches; Mme. Victor Noury foundation between André Lwoff for his work on the physiology and nutrition of the Protozoa, Louis Corbière for his work in systematic botany and his contribution to the study of Norman flora; François Raoult for his analytical researches on rocks and Joseph Repelin for his geological work in Provence; the Henry Le Chatelier foundation to Paul Bastien for his researches on the alloys of calcium, niobium and gallium; the Roy-Vaucouloux foundation to Albert Brault for his studies on glycogen in the development of tumours, normal tissues and organised beings; the Charles Frémont foundation to M. and Mme. Albert Thomas for their researches on a photo-electrograph for the use of the blind.

THE LOUTREUIL FOUNDATION

1. *Researches on Definite Problems.*—5,000 francs to Marcel Brillouin for carrying out numerical calculations relating to the theory of dynamic tides; 2,000 francs to Paul Dechambre for continuing his researches on the physical properties of wool; 5,000 francs to M. and Mme. Joliot-Curie for travelling and other expenses in connexion with their work on physics at the Jungfraujoch station; 2,000 francs to Gustave Lesbouyries for the study of the diseases of birds due to filtrable viruses; 2,500 francs to Lucien Panisset and Goret for their researches on infectious anæmia of the horse; 5,000 francs to Marcel Petit for assisting his researches in comparative anatomy; 5,000 francs to Mme. Lucie Randoin for researches on vitamins; 2,000 francs to Victor Robin for researches on radiodiagnosis and radiotherapy in animals; 3,000 francs to Mme. de Vomecourt for assisting work to be done in the New Hebrides.

2. *Voyages and Explorations.*—15,000 francs to Camille Arambourg as a contribution to an expedition to eastern Africa; 9,000 francs to Auguste Chevalier as a contribution to a botanical expedition to Central Africa; 5,000 francs to Jacques Petit for an expedition to Madagascar.

3. *Purchase of Material.*—8,000 francs to the Lyons National Veterinary School for the purchase of a cinematograph apparatus; 3,000 francs to Augustin Mesnager for the purchase of an apparatus showing the distributions of strains in elastic solids; 5,000 francs to Albert Granger for the purchase of a furnace.

4. *Libraries.*—4,000 francs to the Toulouse National Veterinary School for its library; 6,000 francs to the Polytechnic School for its library; 10,000 francs to the Botanical Society of France for the establishment of a card catalogue of its library.

5. *Publications.*—5,000 francs to the National and University Library of Strasbourg for preparing and printing a catalogue of periodicals; 4,000 francs to the Astronomical Observatory of Zò-Sè, for its publications; 9,000 francs to the National Acclimatisation Society of France for the publication of a book by (the late) Rollinat on the biology of the reptiles of central France; 5,000 francs to the widow of Jean Thomas for the publication of a book dealing with his work resulting from the expedition between the Congo and Lake Tchad.

Instability of Liquid Surfaces

THE problem of the instability of the 'liquid surface' separating two media has fascinated and attracted many investigators but the complexity of the phenomenon as seen in the laboratory and in everyday life, as well as the difficulty of the mathematics, have made progress very slow in the direction of a solution.

A reference to the instability of the surface of separation between two fluids is first found in a paper by Helmholtz[1], and Kelvin[2] in an investigation of the influence of wind on waves in water, supposed frictionless, discussed the conditions under which a plane surface of water becomes unstable. Adopting a suggestion due to Kelvin, Rayleigh[3] investigated the instability of such a surface and obtained results which by now are classical. To a first approximation, the system is unstable for all wave-lengths and the amplitude of an initial displacement of the form $y = a\cos kx$ increases exponentially with the time. The first approximation, however, shows no tendency in the direction of the formation of vortices, but a recent investigation by Rosenhead[4] shows that the tendency towards rolling up is apparent if account is taken of second order terms in the approximation. In order to obtain the ultimate form of the surface of discontinuity, Rosenhead departs from the Rayleigh method and by means of an approximate numerical process demonstrates the formation of vortices. This method, however, does not discover the wave-length which ultimately becomes dominant in the system and so fixes the distance between successive vortices.

Banerji and Ghatage have now investigated the motion of the 'liquid surface' separating two portions of the same medium which are at different temperatures.[5] The account of the investigations is illustrated by a number of excellent photographs showing the rolling up of the surface of discontinuity into vortices, and the separate convolutions can easily be seen. There are also several tables of numerical results which can be used when we have a complete theory capable of explaining the rolling up and of giving the value of the dominant wave-length or wave-lengths.

Previous investigators, theoretical and experimental, seem to have concentrated on discussing the surface separating two streams of equal temperature but differing velocities. Banerji and Ghatage supplement the existing information by investigating the effect of a difference in temperature in addition to the difference in velocity. The results, some of which might have been expected on general grounds, are interesting. A discontinuity in temperature alone, and hence a discontinuity in density, was introduced by making a cylindrical or rectangular column of water in a large tank differ in temperature from the adjoining fluid. Discontinuities in velocity as well as in density were produced by making two streams of water meet at various angles under different thermal conditions.

In all cases the initial surface of separation was in a vertical plane and not, as in most previous work, in a horizontal plane. This makes the basic motion unsteady, so that the surface of discontinuity has a tendency to change its position quite apart from its inherent instability. The instability, however, was quite apparent. The surface assumed a wave pattern, each crest or trough took up the form of a breaker and rolled round itself, thus producing a vortex and a series of spiral-shaped three-dimensional vortices was formed. "In the direction of motion the vortices showed a progressive increase in dimensions and number of convolutions. The greater the difference of temperature at the surface of discontinuity, or the greater its slope, the smaller was the diameter of the vortices. For very small difference of temperature the vortices had enormous diameters. The greater the difference of temperature at the surface of discontinuity, the more rapidly did the vortices develop." The shape of the surface of discontinuity was obtained by colouring various parts of the liquid and by photographing the visible stream lines in horizontal and vertical sections. The paths of the particles at the surface of discontinuity were also photographed but the actual material used to make the motion visible probably has some small influence on the paths of the particles of fluid.

L. ROSENHEAD.

Population Density and Egg-Laying in Flies

IN a paper of much interest, Prof. Raymond Pearl has made a study of the influence of density of population upon egg production in Drosophila (*J. Exp. Zool.*, vol. 63, No. 1), which is a continuation of his investigations on the biological relations underlying the growth of populations.

The flies were placed under standard conditions and deposited their eggs on an agar surface of fixed area where they could be counted. In general, the higher the number of pairs of flies in a bottle of given size the smaller the number of eggs laid per individual. This result, obtained with different populations of flies, was then repeated by comparing the egg production of the same flies when kept for alternating twenty-hour periods under conditions of high or low population density. More than 100,000 eggs were counted in these experiments.

The decrease in the rate of egg production with increasing density of population is described by the same type of mathematical equation as that which relates the density of a gas to the mean free path of its molecules. From numerous observations of the behaviour of single flies under isolated conditions, they are found to go through regular cycles of feeding, walking or flying, resting and cleaning their legs. These rhythms are easily disturbed and the flies are found to be extremely sensitive to slight environmental disturbances. The denser the population the more they interfere with each other's rhythmic activities, thus decreasing the amount of food intake and oviposition and increasing their muscular activity. That the area of agar surface for feeding and egg-laying, and not the volume of air, is the significant factor, was shown by comparing the oviposition in bottles of twice the size but with the same area of agar.

In the same journal, Dr. Alpatov has investigated egg production in vestigial- and long-winged flies under different conditions of development, the former showing much lower productivity. The influence of temperature and underfeeding in the larval stage were investigated. At a low temperature, egg production begins earlier. Underfeeding reduces productivity, and a negative correlation is found between length of life and egg production.

Mycorrhiza on Conifer Roots

A VERY thorough study of the root system of young conifers has been made by Dr. E. V. Laing for the Forestry Commission, and an account of this work is published by the Commission as Bulletin 13 under the title of "Studies on Tree Roots" (1932). This account contains an interesting contribution to our knowledge of mycorrhiza on these roots.

There are two forms of mycorrhiza; the ectotrophic, in which the fungus grows mainly on the surface of the root, and the endotrophic, in which it penetrates the cells of the cortex practically as far inwards as the endodermis. Dr. Laing points out that whilst both forms may occur on the same tree yet, on the whole, the ectotrophic type is common in pine, spruce and larch, whilst the endotrophic type is characteristic of *Cupressus*, *Thuya* and *Taxus*. This distribution of the fungus correlates in an interesting manner with differences in cortical structure. In the first group of conifers the cortical cells have thin walls and contain little starch; in the second group characteristic girdle thickenings occur on the walls of the cortical cells and these cells usually contain starch; this is the type of cortex which is usually invaded by the fungus.

Dr. Laing's investigations also point to the significance of aeration conditions in the soil and manurial treatment in determining whether fungus and root system shall enter into the characteristic mycorrhizal relation. The conditions favouring mycorrhizal infection of the roots also favour vigorous growth of the young tree, so that it remains difficult to assess the significance of the fungus partner in the development of the tree.

A progress report upon investigations into the same problem was presented to Section K (Botany) of the British Association at the York meeting by a committee, of which Dr. M. C. Rayner acted as secretary and Mr. F. T. Brooks as chairman. The work initiated under this committee is now being continued with the aid of a grant from the Forestry Commission, and the results of this work will doubtless be published more fully by Dr. Rayner in due course.

In the report it is stated that soil innoculation experiments have now provided convincing evidence of a direct relation between mycorrhiza formation and satisfactory seedling growth in the case of three species of pines, Scots pine, Corsican pine and maritime pine. From the practical side, the work of the committee has been devoted largely to an examination of the effect of the addition of humus to the nursery beds of tree seedlings, with the view of improving root development and mycorrhizal infection.

University and Educational Intelligence

Cambridge.—The Sir William Dunn readership in biochemistry has become vacant by the resignation of Prof. J. B. S. Haldane. Candidates for the readership, the stipend of which is £600 a year, are requested to communicate with the Vice-Chancellor on or before February 18.

Edinburgh.—The Cameron prize for advance in knowledge in practical therapeutics for 1933 has been awarded to Dr. George F. Dick and Dr. Gladys H. Dick, of the John M'Cormick Institute for Infectious Diseases, Chicago, jointly, in recognition of their work on the etiology and treatment of scarlatina.

London.—Prof. L. N. G. Filon, Goldsmid professor of applied mathematics and mechanics in the University (University College), has been elected Vice-Chancellor for the remainder of the year 1932–33 in succession to the late Mr. J. L. S. Hatton.

The title of reader in experimental physiology in the University has been conferred on Mr. H. P. Gilding, in respect of the post held by him at University College.

Mr. Frank Arnold Greene has been appointed a fellow of King's College. Mr. Greene was a student in the faculty of engineering from 1891 until 1894; he is treasurer of the Institution of Chemical Engineers, and a member of the College Chemical Engineering Committee.

In the eighth annual report to the Court of Governors of the London School of Hgyiene and Tropical Medicine, Keppel Street, W.C.1, various changes in the personnel of the Court and of the Board of Management are recorded. Sir Austen Chamberlain becomes chairman of the Court in succession to Sir Holburt Waring, who becomes honorary treasurer to the Board of Management. The minimum annual expenditure to which the School is committed is £60,000, towards which there is a reasonably assured income of £50,000, leaving a deficit of £10,000 to be met by subscriptions and donations. A grant of 25,000 dollars for 1932 was received from the Rockefeller Trustees. In the report by the Dean, Prof. W. W. Jameson, on the year's work of the School, the teaching and research activities are surveyed, examination results are recorded, and a list of papers published by members of the staff is appended. It is announced that the Prudential Assurance Company has endowed for a term of seven years the chair of public health, which will henceforth be known as the "Prudential Chair of Public Health". A syllabus containing full particulars of the post-graduate instruction in preventive medicine given at the School is issued and may be obtained on application to the Dean.

Calendar of Nature Topics

The First 'Buchan Cold-Spell'

February 7–14.—In 1869 the late Dr. A. Buchan, from an analysis of observations of temperature in Scotland, concluded that "there are certain periods more or less well-defined, when the temperature, instead of rising, remains stationary or retrogrades; instead of falling, stops in its downward course, or even rises; and at other times falls or rises respectively for a few days at a more accelerated speed than usual". Buchan attributed these variations to the alternations of cold and warm air currents, but several other more or less fanciful explanations have been put forward by different authors, all of whom took the reality of the 'spells' for granted. A recent investigation has shown, however, that in London since 1870 there has been no definite tendency for temperature to be abnormally low on the dates of Buchan's cold spells, the period February 7–14, for example, having been warm as often as it was cold.

Fish Culture

"Feb. 9th, 1863.—Eggs of first lot of Rhine salmon hatched out in my bath." (Buckland, Diary.) The middle of last century saw a great revival in European countries of the ancient art of pisciculture. The work of Coste and the establishment by the French Government in 1848 of a hatchery at Huningue near the Rhine and Rhône Canal led to a widespread interest in salmon and trout rearing. In 1853, Dr. Garlick of Ohio first bred fish artificially in the United States, and in the same year the well-known Stormontfield establishment on the Tay came into being. In England, Buckland, later H.M. Inspector of Fisheries, took up the idea with great enthusiasm. During the past eighty years, fish culture has developed commercially on a very large scale especially in America.

Partridge Disease

The partridge season which has just closed will be memorable for the prevalence and the investigation of partridge disease. Beginning noticeably in the autumn of 1930 the disease spread widely and caused heavy mortality. Examples of its incidence in 1931 on various estates are—in Hampshire of a stock of young and old birds numbering 3,000, 2,000 perished, in Norfolk 4,200 perished out of 5,000, in Suffolk 2,600 out of 3,467, in Derbyshire 2,200 out of 2,500, in Nottinghamshire 10,100 out of 12,000. *Country Life* appointed a committee under the chairmanship of Major M. R. Portal to investigate the disease and the findings have recently been published under the editorship of Major Portal and Dr. W. E. Collinge. While partridges have several internal parasites, the cause of the widespread disease is a nematode worm, *Trichostrongylus tenuis*, a near relative of the agent of grouse disease, *T. pergracilis*. Like the latter, the partridge strongyle lives in the caeca, causing blockage and the production of septic conditions. Exceptionally, as many as 12,226 and 10,500 individuals have been found in single birds, but a count of 1,000 to 2,000 marks a more usual infestation. In the caeca the worms pair and after the eggs are laid they pass out with the fæces and develop into larvæ which make their way up the damp stems of grasses, clovers and such like. With vegetable matter they are swallowed by the partridges and the cycle begins again in the bird's intestine. The Committee has reached the conclusion that predisposing causes of the spread of the disease were interbreeding, the carrying of large winter stocks, an insufficiency of food, and peculiarly unfavourable meteorological conditions.

Fluctuations of Partridge Numbers

It is notorious that the numbers of partridges on an estate may show great changes from year to year, and periods of great plenty and of great scarcity seem to follow each other in cycles. In the game book of one of the great landowners in Britain, ignoring the years before partridge driving began (about 1845), there are enormous swings of the partridge pendulum: in 1864, 634 birds were shot, the numbers rose to a peak in 1870 with 3,741, but by 1879 they had fallen, gradually, to 359; another steady rise, and in 1887, 5,360 were shot and in 1896, 5,478. Such totals have not since been reached on these estates and later figures suggest a tendency for the annual bag to become smaller. The complicated factors of weather, food, natural enemies and disease, which influence the numbers from year to year, have not yet been resolved, but there can be little doubt that the modern trends of agriculture and transport are likely to make permanent inroads upon the partridge population. The partridge is a bird of cultivated land, and the intensive cultivation which ploughs a field to its very borders and replaces hedgerows by fences, has destroyed the rough herbage which was a favoured nesting site. Extensive turning of crop land into pasture has removed a source of food, as well as protective cover for the nests and young, and grass conceals the fine grit essential for the grinding of food, which the plough laid bare. New forms of road surface have done away with another source of grit, and have banished favourite dust baths, also reduced by the grass lands. The cleaning up of the roadsides and the removal of hedges have removed former nesting places, and the fast traffic of the roads is directly responsible for a certain amount of mortality. In face of such adverse factors, it would be surprising if the stock of partridges were not to decline, unless steps are taken to minimise their influence. This is a very simple illustration of the way in which the native fauna of the country may be undergoing modification.

Societies and Academies

LONDON

Royal Society, Jan. 26. J. Z. YOUNG: Comparative studies on the physiology of the iris. (1) Selachians (second paper)—*Uranoscopus* and *Lophius*. The sphincter iridis muscle of *Scyllium*, *Mustelus* and *Trygon* contracts in direct response to illumination and is not under nervous control. The iris of *Lophius piscatorius* and also that of *Uranoscopus* is capable of rapid movements under nervous control, the oculomotor dilating and the sympathetic constricting the pupil. S. G. PAINE, F. L. LINGOOD, FREDA SCHIMMER and T. C. THRUPP: The relationship of micro-organisms to the decay of stone. Three groups of bacteria have been distinguished. In the first group are included common organisms of air, soil, and water. These organisms are capable of living on a variety of food materials, and in their metabolism acid substances are formed as waste products; these acids, even when the food supply is merely the small amount of organic matter present in rain water, can dislodge carbon dioxide from its combination with calcium in the stone. In the second group some confirmation is to be found of the view of Marsh that nitrifying bacteria can be responsible for stone decay. In the third group are the sulphur-oxidising organisms which have been found closely associated with white incrustations of sodium and calcium sulphate on the surface of decaying stones. W. J. ELFORD: The principles of ultra-filtration as applied to biological problems. The several factors concerned in the general process of filtration have been investigated, using typical disperse systems—colloidal dyes, metal sols, protein solutions and suspensions of bacteria and viruses. The relationship between the size of retained particles and the estimated pore sizes of membranes is also discussed. The fact that, for colloidally dispersed systems, the pore-size of the limiting membrane is definitely greater than the size of the retained particle, even under optimum filtration conditions, is in accordance with theoretical expectations. The particle sizes of suspensions, estimated from filtration experiments with carefully graded collodion membranes, agree well with the values obtained by other methods. The method of analysis adopted has proved of great value in virus studies.

PARIS

Academy of Sciences, Dec. 19 (195, 1185-1335). MARCEL BRILLOUIN: Multipolar spherical non-antipodal functions. Recurrences. L. CAYEUX: The existence of a phosphate containing spicules of Calcisponges in the Ordovician of Wales. MARIN MOLLIARD: Experiments permitting an explanation of the attenuation of the chlorophyll shown by parasitic green plants. Results of experiments comparing the growth of the radish in a medium of carrot decoction and in Knop's fluid containing saccharose. About ten times as much chlorophyll appeared in the leaves of the plants grown in the latter medium as in leaves from plants grown in the carrot decoction. L. BLARINGHEM: A case of atavism which appeared in a strain of the opium poppy. One example, in 5,000 strictly isolated individuals, of reversion to a type known three centuries ago, showed a change to white petals bordered with red. CHARLES ACHARD and AUGUSTUS BOUTARIC: Some physico-chemical researches on suspensions prepared starting with proteins separated from serum by the so-called acetone method. From the results of the experiments described, the authors conclude that the separation of the proteins by the acetone method of Piettre and Vila causes no changes in the protein molecules. R. FOSSE, P. DE GRAEVE and P. E. THOMAS: A new plant principle: uric acid. Uric acid has been found in a mould but, according to Czapek, is not present in the higher plants. Using a technique given in detail, the authors have proved this acid to be present in various plants in quantities ranging from 0·003 per cent in *Glycina soja* to 0·025 per cent in *Melilotus officinalis*. CHARLES CAMICHEL: Transitory [hydraulic] regimes. M. GIGNOUX and L. MORET: The geological structure of the base of the Flysch sheet of Embrunais in the Ancelle valley, near Gap (Hautes-Alpes). JULES RICHARD: The use of the Cattaneo wave pump for utilising the movements of the sea. Diagram and description of the pump, which has raised 495 litres an hour to a height of 51 metres. L. LÉGER and T. BORY: The parasitism of an *Oscillaria* in the intestine of the carp. LALAN: The asymptotic transformations of minimal curves. PAUL MONTEL: A theorem of Rouché. GEORGES BOURION: Ultra-convergence in certain series of analytical functions. J. FAVARD: The topological structure of rectifiable contina. A. KOSTITZIN: A geological application of differential equations. D. BELORIZKY: The representation of certain functions by particular series of polynomials. J. GRANIER: The influence of vibration on the rate of watches. P. DUPIN and M. TEISSIÉ-SOLIER: The vortices produced by obstacles revolving round an axis parallel to the general direction of flow. Reproductions of a photographic film are given showing the changes in the shapes of the vortices. MAX SERRUYS: The determination of some physical characters of detonation showing its local character. A. GREBEL: A diagram representing the true phenomena of compression, combustion and expansion in high speed motors. V. G. SIADBEY: The determination of meteoric trajectories. HENRI MINEUR and ANDRÉ MACHIELS: The distribution of the absorbing galactic material. F. LINK: The photometric study of the partial eclipse of the moon on September 14, 1932. Tabulated results of observations made at the Pic du Midi Observatory (height 2,860 metres). ROLIN WAVRE: The polydromes of the Newtonian potentials of a family of homogeneous bodies. A. LABARTHE and M. DEMONTVIGNIER: Methods of measuring and recording rapidly variable pressures. A ray of light falls on a mirror forming part of the wall of the space in which the pressure is to be measured: the reflected ray falls on a photoelectric cell, the currents from which are amplified in the usual manner. Successful applications to studying the pressure changes inside the cylinder of an internal combustion motor are described. JAMES BASSET: The realisation of a chamber for experimenting at any temperature under permanent gaseous or liquid pressures up to 15,000 kgm./cm.^{2} with visual observation of the phenomena and with photographic or cinematographic registration. PIERRE VERNOTTE: The natural convection of heat in air when the heating is very small. The comparison of the limiting value of the convectance with the thermal conductance of the medium. PIERRE DAVID: The radiation of the radiotransmitter of the Eiffel Tower. A study of the radiation shows that the metallic parts of the Tower are the seat of important currents, modifying the radiation in an unexpected manner. HORIA HULUBEI: Demonstrating multiple Compton diffusion. PAUL WOOG and RENÉ SIGWALT: The use of the Duboscq colorimeter for the definition of colours by analysis in different parts of the spectrum. A. NAHERNIAC: The study of a phenol–OH band in the near infrared. T. N. PANAY: An integral radiator (black body) of electrically heated carbon. The apparatus described and figured can be worked at temperatures of the order of 2400° K. It embodies a special device to obviate the necessity of the electrical conductors being sealed into the glass container. Q. MAJORANA: The confirmation of the existence of a new photoelectric phenomenon. C. JAUSSERAN: The action of a developer on latent images of different ages. R. COUSTAL and H. SPINDLER: The electrolysis of dry liquid ammonia. GEORGES FOURNIER and MARCEL GUILLOT: The absorption of the β-rays by matter. The relation between absorption and atomic number given in a previous note is now shown to hold for platinum and lead. P. LECOMTE DU NOÜY: Improvements to the hydrogen electrode for the measurement of hydrogen ion concentration in solutions. A method by means of which the platinising and hydrogenation of the electrode can be dispensed with. A. LALANDE: A new cryoscopic method. R. TREHIN: The influence of temperature on the absorption of aqueous solutions of hydrochloric acid in the extreme ultra-violet. The coefficient of molecular absorption is a function of three variables: wave-length, concentration and temperature. J. HERENGUEL and G. CHAUDRON: The sublimation of magnesium in a vacuum and casting in an atmosphere of argon. By means of the apparatus described and illustrated, ingots of magnesium of 26 kgm. can be prepared. PICON: Preparation and properties of thallous thiocarbonate. A specific reaction of thallium. This compound is easily prepared by adding carbon disulphide to thallium sulphide in alkaline solution. It is a vermilion red precipitate, formed in very low concentrations of thallium, and serves as a means of identifying thallium. HENRI LAFUMA: Hydrated bicalcium aluminate. FIRMIN GOVAERT: The estimation of the halogens in organic substances by the sodammonium method. The estimation of fluorine in some organic compounds. The method is shown to be widely applicable. ROBERT CAMBIER and LUCIEN LEROUX: The estimation of organic nitrogen in the presence of nitrates by Kjeldahl's method. The nitric acid is first removed by acidifying with sulphuric acid and distillation in a vacuum at a low temperature. R. SUTRA: The structure of starch. TIFFENEAU: Molecular transpositions in the cyclohexane series: passage to the cyclopentane series. MME. M. GUAISNET-PILAUD: The phenylmethyl-ethyl betaines and the geometrical stereoisomerism of organic compounds containing pentavalent nitrogen. R. PAUL: The stability of the oxygen linkage in the tetrahydrofuryl derivatives. M. BATTEGAY and L. DENIVELLE: The aryl-chlorsulphinates and aryl sulphites. Criticism of a recent paper by P. Carré and D. Liebermann. E. AUBERT DE LA RÜE: Preliminary study of the geology of the Saint-Pierre and Miquelon Islands. R. DELABY, R. CHARONNAT and M. JANOT: The radioactivity of the waters of the Ballon d'Alsace. ALPHONSE LABBÉ: The hydrogen ion concentration and rhythm of the tides. R. GUIZONNIER: The diurnal component of the gradient of electric potential at Val-Joyeux. The variations of its phase and amplitude. ANDRÉ ALLIX: The progressive darkening of the Lyons atmosphere. The visibility of the Alps. A comparison of the periods 1894–1900 and 1925–1931 shows a distinct decrease in the transparency of the atmosphere. Paul Bertrand: Observations on the Saalfeld *Cladoxylon*. St. Jonesco: The movements and growth of the flower peduncles of *Ipomœa purpurea*. Marcel Lefèvre: The structure of the membrane of *Euglena* of the *Spirogyra* group. Pierre Chouard: The diversity of types of seedlings in *Allium*. Michel Gračanin: Ion concentration as a factor in resorption. H. Colin and M. Quillet: The jelly of the egg of *Phallus impudicus*. J. Chaze: The exudation of the alkaloids of *Lupinus albus*. Mlle. C. Bourdouil: The relation between the synthesis of starch and the weight of the seeds in hybrids of *Pisum*. Robert Lemesle: New researches on *Scabosa Succisa* attacked by *Fusarium anthophilum*. Mme. F. Franck and D. Auger: The cinematographic analysis of the movements of protoplasm in relation with the electrical variation in stimulation in *Nitella*. Charles Pérez: Intersexual anomalies in hermit crabs. Mme. Jeanne Henri-Heldt: The male genital apparatus of North African shrimps of the family of Penæidea. Mme. L. Randoin and H. Simonnet: The constitution of an artificial diet for the purpose of long-period experiments on the relations between nutrition and the phenomena of growth, subsistence and especially reproduction. Raymond-Hamet: The action of tyramine on the excitability of the cardiac pneumogastric and the influence of this amine on the effects of nicotine. Mlle. M. L. Verrier: Comparative physiology of the cones and rods. Indications given by behaviour.

Forthcoming Events

Monday, Feb. 6

University College, London, at 5.30.—H. W. B. Joseph: "Space Perception" (succeeding lectures on Feb. 13 and 20).

Society of Engineers, at 6—(at the Rooms of the Geological Society, Burlington House, W.1).—J. D. Hawort: Presidential Address.

Royal Geographical Society, at 8.30.—Capt. Ejnar Mikkelsen: "The Blosseville Coast of East Greenland".

Tuesday, Feb. 7

King's College, London, at 5.30.—Dr. F. T. Chapman: "Induction Motor Theory" (succeeding lectures on Feb. 14 and 21).

Thursday, Feb. 9

Bedford College, London, at 5.15.—"Contemporary Developments in Science." Prof. E. T. Whittaker: "The Development of the Concept of Energy in the Twentieth Century".

Friday, Feb. 10

Royal Astronomical Society.—Dr. H. Knox-Shaw (Presidential Address): "The Distance and Motions of the Extra-Galactic Nebulæ".

Royal Institution, at 9.—Prof. A. V. Hill: "The Physical Nature of the Nerve Impulse".

Rubber Research

FREQUENT reference has been made in our columns to the importance of the relations between the State and industry in regard to research. Abundant evidence has been quoted to show that research on materials, methods of manufacture, and the properties of finished products not only benefits the industry concerned but also, directly and indirectly, the whole nation. Recognition of this common interest in research was shown by the grant in 1916 of a special fund to initiate and encourage co-operative research in Great Britain, and by the continuation of grants to the industrial research associations, which came into existence as a result of this policy, long after the end of the trial periods originally contemplated.

We are reminded of this community of interest by the announcement that the thirteen years' partnership between the rubber manufacturing industry and the State, through the Department of Scientific and Industrial Research, is to be dissolved unless assurance is immediately forthcoming that the finances of the Research Association of British Rubber Manufacturers can be established on a stable and adequate basis. The situation demands attention particularly because the fate of the Association now appears to rest with the House of Commons and possibly with the Government.

The Association, initiated in 1919 with fifteen members, has now grown to a membership of eighty-six firms, and is supported in addition by ninety-five subscribing firms and institutions interested in rubber but not qualified as actual manufacturers for full membership. A summary of the twelfth annual report was given in our columns (NATURE, 129, 695, May 7, 1932), and from this it is evident that the Association has made itself increasingly useful, not only to its own members, but also to other trade and research associations and Government departments.

In recent years the financing of the Association has become increasingly difficult, partly owing to the industrial depression and partly owing to the constitution of the industry, consisting as it does of a large number of firms varying greatly in size. Some of the larger units, which have supported the Association both financially and scientifically from the beginning, are capable of carrying out research economically in their own factories and therefore take the view that they cannot continue to finance the Association in the common interest, except under some scheme by which all members of the industry contribute on a proportionate scale. To this end the Association has prepared a scheme by which it would be financed by the proceeds of a levy of one forty-fifth of a penny per lb. on all raw rubber imported into Great Britain, thus spreading the burden uniformly over the units of the whole industry in proportion to their rubber consumption. This levy would secure an annual income to the Association of about £15,000. The scheme has been accepted by the majority of the firms in the industry and approved by the principal trade associations.

The financing of research or development by a levy on a basic material is not without precedent. The Cotton Industry Act of 1922 provides for the encouragement of cotton-growing in the British Empire by a levy on raw cotton; there is a cess on exported rubber for the upkeep of raw rubber research in Ceylon; and there is a levy on coal by which the Miners' Welfare Fund is financed in Great Britain. The idea of a levy for the support of a research association has also been considered favourably by more than one Parliamentary Committee. In its Final Report, the Balfour Committee on Industry and Trade stated:

> "We have watched with interest and sympathy the steps taken by the rubber industry to secure the necessary funds for the operation of its research Association through a small levy on imported rubber. We hope that this scheme will receive legislative sanction, and that it may serve as an example to other industries to adopt measures, suited to their special conditions, for placing the finances of their research Associations on a permanently satisfactory basis."

Again, the Committee on New Industrial Development stated in its report:

> "We do not consider that any general powers should be taken to enforce compulsory levies for the support of research Associations. Should an industry, however, succeed in working out a practicable scheme involving a compulsory levy for the support of a research Association, which it can show commands the support of a substantial majority of the industry, including the larger concerns, we consider that the Government should be ready to assist the Industry in obtaining the necessary Parliamentary powers."

The proposal for a levy in this case is embodied in the Rubber Industry Bill and has been four times before the House of Commons. When it was last debated, about two years ago, the opposition was based mainly on the objection of certain firms to compulsory support of an organisation which they considered to be of no value to them. In spite of this objection, the Bill obtained a second reading majority of 148 votes to 10 and passed through Standing Committee, but did not receive a third reading owing to lack of private members' time before the end of the session.

During the past year, a significant change in the situation has occurred. Many British industries, including the rubber industry, are now protected in the home market by a general tariff. Consequently, the technical efficiency of an industry cannot now be regarded as a purely domestic question for the industry itself. Whatever views might have been held a year ago on what the opposing firms called "the inalienable right of the British trader to carry on his trade without interference", it will be agreed that a protected industry should take a much less individualistic view of its obligations to the community, which voluntarily surrenders its right to carry on its buying without interference. In consideration of the benefits conferred by a tariff, the consumer has the right to expect the industry to give its best in return, and will not be greatly impressed by the plea of a minority which objects to a levy amounting on the average to about 1/1800th part of the selling value of its products for the purpose of improving the scientific and technical efficiency of the industry. In these circumstances, there is little doubt what the verdict of the House of Commons would be if the Bill were to obtain another debate and division.

Unfortunately, this seems unlikely to occur; for the prospects of the passage of a private member's Bill against even the slightest opposition are so small that arrangements have already been made for disbanding the staff of the Research Association when its financial resources are exhausted at the end of this month. If the organisation is to be kept together, action must be taken quickly and the only course now left open seems to be for the Government to declare itself in favour of the principle of the Bill and give it facilities for passing through its further stages. Indeed, considering the dependence of all the industrial research associations on State assistance, it is surprising that the Government, once it adopted tariffs, failed to earmark a part of the revenue thus obtained for the more earnest prosecution of research in every branch of industry.

The Cost of a New World Order

After Democracy: Addresses and Papers on the Present World Situation. By H. G. Wells. Pp. vii + 247. (London: Watts and Co., 1932.) *7s. 6d.* net.

IN this volume of essays, all the product of the last three years, we have the revelation of the thoughts on our present discontents of a student of science turned publicist and perhaps the most qualified of living writers to express either the implications of the scientific outlook in the life of society or the responsibilities which fall on the shoulders of scientific workers.

There is little sequence or relation between the essays other than that conferred by the author's outlook. They range from parliamentary government, economics, planning and world peace to divorce and morals. Each subject is touched upon in the same openmindedness and readiness to accept the consequences of change and development. Mr. Wells reiterates repeatedly the significant facts which our whole system of government and industry are still disposed to burke—the abolition of distance, the growth of human life into a world-wide community of interdependent human beings—and he has no patience with the prejudices or the stupidity which refuse to accept the situation and to meet the consequences, above all with the neglect of the sovereign governments of the world to accommodate themselves to this fusion of once separate economic systems.

This impatience is apt at times to lead to excessive depreciation of factors which may have real value in the scientific order of society which he visualises as essential for the security of mankind. Thus Mr. Wells's denunciation of the evils of nationalism, and his exposure of its persistent menace alike to world peace and to the economic structure of mankind, lead him to repudiate internationalism almost as forcefully. Is this either logical or wise? The international spirit as evidenced in certain forms of world co-operation, such as the health work of the League of Nations, shows itself at least as practicable as the cosmopolitanism to which Mr. Wells leans so strongly and is at least as likely to promote the development of the sense of world citizenship. A sense of civic and municipal responsibility or pride can be a national asset provided it does not displace or overshadow the larger and greater loyalty to the State as a whole. Nor need we assume that if we succeed in stripping our national governments of their militant manifestations, whether in military pageantry, armaments or tariffs, the national units may not learn to co-operate effectively and wisely for the good of mankind as a whole. The League at least offers a framework for constructive work, once the militancy of national governments has been replaced by a spirit of co-operation alike in the direction of a world police force or a world economic policy.

So, too, Mr. Wells's well-founded distrust of nationalism leads him to deny or ignore all its spiritual aspects and the rich contribution to civilisation made within the national framework. To the thinker, no doubt the vision of a world State and the allegiance of world citizenship may make a direct and a nobler appeal. But to lesser minds, the lesser loyalties may be more concrete, and rightly orientated may make the more effective appeal. We may yet see the day when the ordinary citizen is proud of his country according to her reputation for honourable dealing and co-operation in the world comity of nations in the same way that he is careful of his own reputation as a just and law-abiding citizen.

If Mr. Wells has dealt with internationalism with rather unmerited severity, his strictures on the rising tide of nationalism and the many agencies that minister to it are well deserved and should indeed be supported and echoed fearlessly by all who wish to see a scientific order of society. The most significant note in the book is indeed to be found in the emphasis placed on education. It is only as man comes to an accurate knowledge of his environment and relates his knowledge to that action that Mr. Wells sees any hope for the world.

Nowhere in the book is this more clearly stated than in the addresses on "Liberalism and the Revolutionary Spirit" and on "The Commonsense of World Peace". In a footnote to the former address Mr. Wells outlines again the ideas recently formulated under the title "The Open Conspiracy". The basis of his "*Z* Society" is declared to be "the discussion, study, research and propaganda of the sciences of social biology" and "the effective application of their principles to the reorganisation and enlargement of human life". This is nothing else than a challenge to honest, lucid thought about the facts of the situation, and that is basic for the liberation of the world from sectionalism whether national or lesser units are involved. So, too, the basis for world peace lies in the elimination of nationalist teaching and teachers everywhere—the development of a history teaching which leads us on to the great possibilities of the collective human future. "We need an education that will turn mankind from tradition to hope".

Here indeed Mr. Wells is on firm ground, and if his appeal succeeds in stimulating the wide circle of readers, into whose hands his reputation should carry the book, into thinking out some of these implications for themselves, and into refusing to tolerate the wrong kind of teaching or the perpetuation of obsolete jealousies, and sectionalisms, the first steps towards the new order will have been taken. There is no need to dwell on Mr. Wells's obvious failure to show how the minority dictatorship he conceives in his "Z Society" is to succeed while conceding full freedom of thought and expression. Once the vigour of mind, the willingness to accept new situations, to discard old prejudices, which characterise the distinguished author of this book have gained a firm hold on the minds of men generally, we should be in a fair way to realise his vision. But time presses and the danger that before any such widespread movement of thought can occur our civilisation may have tottered to its ruin, is even more acute than Mr. Wells suggests in his somewhat pessimistic sketch "Our World in Fifty Years Time". It is in fact difficult to see how the vested interests blocking the way to world security can be overcome except as governments are captured through the rapid orientation of some major political party to the outlook for which he pleads. To that orientation scientific workers everywhere might even yet contribute the decisive factor.

R. BRIGHTMAN.

An Imperial City of China

Jehol: City of Emperors. By Sven Hedin. Translated from the Swedish by E. G. Nash. Pp. xiv + 278 + 63 plates. (London: Kegan Paul and Co., Ltd., 1932.) 18*s.* net.

THIS book has its origin in the desire of the author's fellow-countryman, Mr. Vincent Benedix, of Chicago, to erect a Lamaist temple, either an original or a replica, in Stockholm and another in Chicago. Sir Sven Hedin, to whom the commission was entrusted, elected to make a replica of the Golden Temple in Potala of Jehol, the city which was once the summer residence of the Manchu emperors. The plans and drawings were made and the material collected—even down to the paint—in the summer of 1930 with the assistance of Chinese architects and draughtsmen. At the time this book was being written, the replica for Chicago, with the accessories of the ritual, had reached its destination and was awaiting erection.

The Potala of Jehol was constructed after the model of the Potala, the famous temple-monastery of Tashilhunpo in Tibet, and was completed in the year 1771. Its erection marked two important events, the gathering of the vassal princes and chiefs, who had recently sworn allegiance, to congratulate the Emperor Ch'ien Lung on his sixtieth, and his mother on her eightieth birthday, and the return to China of the Turgot, or Kalmuks, from Russia after an expatriation which had lasted for one hundred and seventy years. This was also the occasion of a visit to the Emperor of the Tashi Lama, the greatest figure in Northern Buddhism of that era. His death while at Jehol was a misfortune for Buddhism.

Sir Sven Hedin has availed himself of the opportunity afforded by his stay in Jehol to produce an illuminating account of that city as a setting for the Manchu spirit of imperial rule. It is situated some 114 miles from Peking, just outside the Great Wall, and has been described as the Fontainebleau of China. The author has made no attempt to describe its many temples, pavilions and ceremonial buildings in detail, but confines himself to a brief account of the Potala, the Hsin Kung temple-monastery, which was erected to accommodate the Tashi Lama when he visited Ch'ien Lung, the "Temple of the Great Buddha", and one or two more of note.

It is, however, on the historical side of his subject that the author is at his best. He deals with the lives of three great figures of the Manchu dynasty associated with Jehol—the Emperor K'ang Hsi (1662–1722), Ch'ien Lung (1736–1796) and the Manchu concubine Yehonala, better-known to Europeans as the Dowager Empress, who dominated China from 1861 almost up to the day of the Republic. In his account of the two emperors who made China one of the great empires in the history of the world, the author has supplemented European sources, which for the most part are readily accessible, by Chinese records, some not previously translated. Here he has had the assistance of Chinese scholars. These documents are a revelation in so far as they indicate the principles of Chinese imperial policy and even more the Chinese point of view in dealing with the western world. Ch'ien Lung's letter to King George III, in reply to Lord Macartney's embassy of 1792, when viewed in the light of these records, may even serve to assist in the interpretation of recent history in the Far East and Chinese international relations in modern times. There is much to be said on the side of China, as well as in extenuation.

A disturbing account is given of, in some instances, the decay, and in others of the destruction, of irreplaceable gems of art and architecture in this now neglected city. The recently aroused interest of China in her antiquities should not be suffered to neglect even the work of the Manchu dynasty.

In two chapters, one dealing with the march of the funeral procession of the Tashi Lama from Jehol back to Tibet, the other with the flight of the Turgot from Russia, the author's wide and intimate knowledge of central Asia has been drawn upon for two of the most graphic and moving pieces of description in an absorbing book.

Modern Genetical Studies

Recent Advances in Plant Genetics. By Dr. F. W. Sansome and J. Philp. Pp. x+414. (London: J. and A. Churchill, 1932.) 15*s*.

GENETICS, in the broadest sense, is advancing so rapidly, and by so many different methods, that it has already become impossible for either the specialised research worker or the teacher of biology to keep in touch with all the latest discoveries and theories by reading the numerous original publications. Moreover, the literature is so scattered through scores of periodicals that only a very large library can contain even an essential part. For these reasons alone the publication of a book, which, though not of the nature of a general textbook of genetics, summarises the results of research, mainly of the last ten years, must be welcomed by a large number of biologists.

Within the limits deliberately set out in the preface, Dr. Sansome and Mr. Philp have chosen their material most judiciously. It is to be regretted that considerations of space made it impossible to deal more fully with sex in plants, chimæras, and the mathematics of inheritance and populations. A clear exposition for the general worker and 'honours student' of the last subject especially would be of very great value, and the hope may be expressed that a supplementary volume to that now under consideration may be published and include both the biometrics of evolution and genetics and a fuller account of the relationship of genetics to the wider problems of evolution.

Throughout the ten chapters the predominance of cytological methods in modern genetical studies is very evident. An extensive study of chromosome numbers and morphology is leading to a more direct investigation of genic reaction than is possible by breeding alone, but the various kinds of genes (or factors) now recognised have still to be designated almost always from the somatic effects they produce and not from their own nature. In the chapters dealing with the chromosome theory of heredity, and those on polyploids, the reader will find a most valuable summary, illustrated with figures and tables, of the more important of the many recent researches showing the close connexion between chromosomes and the appearance and behaviour of characters in plants. The complexity of structural hybrids and the results of interspecific hybridisation in such genera as *Galeopsis*, *Triticum*, *Nicotiana*, *Crepis*, *Viola*, and *Antirrhinum*, can again only be interpreted satisfactorily when breeding results are correlated with cytological investigation.

The long bibliography (47 pages), of properly quoted references, occupying as it does more than one-tenth of the book, indicates how rapidly the subject has advanced in recent years and suggests that there will soon be a need for another work of a similar kind. The chapter entitled "Conclusions" is, therefore, of a tentative but optimistic nature.

The principles of Mendel have been modified or extended in scope but have stood the test of thousands of experiments with the need for less basic alteration than, perhaps, has been needed by any other original biological theory. Recognition of the interaction of factors with one another and the modifying influences of the environment has led geneticists to a unitary biological point of view. Only hypotheses as to the methods of factor action, how ontogeny is genically controlled, are yet available and probably concern the biochemist and biophysicist more immediately than the geneticist. Combined investigations, however, such as those on flower colour in *Dahlia*, will give facts for testing and improving these provisional suggestions. In another direction the application of combined genetical and ecological methods and results to 'species problems' has already opened up a fascinating field where efficient team-work must include the taxonomist and student of geographical distribution.

It is evident that the work under notice should have a wide appeal at the present time, that it fills, at least temporarily, an important gap in English biological literature, and that it should stimulate a wider and deeper interest in a subject of more than academic importance. W. B. T.

Chemical Examination of Explosives

Chemische Untersuchung der Spreng- und Zündstoffe: unter besonderer Berücksichtigung der zu ihrer Herstellung notwendigen Ausgangsstoffe. Unter Verwendung eines von Hermann Kast hinterlassenen Manuskriptes. Herausgegeben von Ludwig Metz. Pp. x + 583. (Braunschweig: Friedr. Vieweg und Sohn A.-G., 1931.) 40 gold marks.

THIS book is practically a demi-official publication as it embodies much of the experience accumulated by the "Centrallstelle für wissenschaftlich-technische Untersuchungen" and the "Militärversuchsamt" up to the time of the Armistice, when they were abolished, and by the "Chemisch-technische Reichsanstalt" which was established afterwards. It is not likely that in any country other than Germany a volume of nearly 600 pages, costing £2 at par, would be published dealing with such a specialised subject. The title does not give a very accurate idea of the scope of the book, for about sixty per cent of it is devoted to smokeless powders and their raw materials and other products which are not strictly either "Sprengstoffe" or "Zündstoffe". The same objection applies, however, to the title of Kast's companion volume "Spreng- und Zündstoffe" published in 1921, which dealt with the manufacture and properties of explosives. Presumably the more comprehensive title "Explosivstoffe" was avoided because it is not a purely German word—an illustration of one of the minor disadvantages of the excessive development of nationalist feeling. The authors, however, have not ignored the work done in countries other than their own.

About half the volume deals with the raw materials used in the manufacture of explosives. Naturally there is nothing very original in these sections, but it will be convenient to the explosives chemist to have the information collected together. It is more in the methods of testing the explosives themselves that the authors' experience will be found of special value.

Some seventy pages are given to stability tests; 40 of these pages dealing with nitrocellulose and 25 with smokeless powders. Like others who have had to deal with this elusive subject, the authors concluded that there is no single test which is really satisfactory, and it is consequently desirable to test a sample by two or more methods. Those favoured, especially for fibrous nitrocellulose, are the well-known Bergmann and Junk test at 132° C. and a storage test at 75° C. In the latter, 5 gm. of the dried explosive is heated in a long stoppered tube for some days until red fumes appear.

In the manufacture of smokeless powders the most important development of recent years has been the introduction of non-volatile gelatinisers which are also efficient stabilisers. They assist in converting the fibrous nitrocellulose into a hard horn-like mass and at the same time act as negative catalysts to the thermal decomposition of nitric esters. Of these substances the most important is "Centralite No. 1", diethyldiphenylurea, which was patented by Claessen so long ago as 1906, but does not appear to have been used on a large scale before the War. Its use enabled the Germans to dispense altogether with the use of volatile solvents in making nitroglycerine powders, and consequently the lengthy drying process was eliminated. With nitrocellulose powders, containing no nitroglycerine, it has not been found practicable to dispense with the volatile solvent, ether-alcohol, because the powder mass is too stiff, even at a temperature of 80° C., to be worked up without danger of explosion. It is, however, added to these powders as a stabiliser, and the surface of the grains is often treated with "Centralite" to make the powder burn in a more progressive manner. Since the War, "Centralite" has been adopted by other countries for the manufacture of their smokeless powders. Kast and Metz give considerable information about the chemistry of this and other similar substances, and a number of methods for its estimation in smokeless powders.

Lead azide, which is now used largely as a substitute for mercury fulminate, is also dealt with adequately. Lead styphnate (trinitroresorcinate), which is added to azide to make it more ignitable, is treated briefly, and some information is given about other comparatively new explosives, such as pentaerythritol tetranitrate.

In consequence of the general plan of the book, the same substance is dealt with in a number of different places, but as there is a good subject index this introduces no serious difficulty. There is no index of authors. ARTHUR MARSHALL.

Short Reviews

(1) *Elementary Textile Design and Fabric Structure.* By John Read. Pp. 95. (London: Edward Arnold and Co., 1931.) *5s.*

(2) *Textile Design and Colour: Elementary Weaves and Figured Fabrics.* By William Watson. Third edition, with Appendices on the Manufacture of Rayon (Artificial Silk) and Standard Yarns, Weaves and Fabrics. Pp. xi+476. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1931.) 21*s.* net.

BOTH these books are restricted to the consideration of elementary weaves; but Mr. Read's is also designedly elementary from the instructional point of view, consisting in the main of a series of exercises, whereby the beginner may proceed, step by step, to gain useful knowledge of his subject, and it is well adapted for the purpose. Mr. Watson's book is of a more substantial character, and it displays a grasp of the technique and is accompanied by a wealth of diagram and illustration, that render its value indisputable, even were the latter not suggested by the fact of this being the third edition.

Mr. Watson, like some other present-day writers, seems to hold a different view as to spectrum colours from that held by Sir Isaac Newton and other pre-twentieth century men of science; he writes of six spectrum colours, in place of seven, and regards green (not yellow) as one of the spectrum primaries; in consequence, his views as to the complementaries also differ. Mr. Read's book would have benefited by a freer use of half-tone illustrations of representative fabrics, such as are so liberally introduced by Mr. Watson. The latter's illuminating description of the Jacquard loom and its practical application, and the appendixes dealing with standard fabrics and rayon manufacture sensibly increase the interest of the work.

P. L. M.

Spencer's Scientific Correspondence with Sir J. G. Frazer and Others. Edited by R. R. Marett and T. K. Penniman. Pp. xi+174. (Oxford: Clarendon Press; London: Oxford University Press, 1932.) 10*s.* net.

IN one sense this volume of letters selected from the correspondence of the late Sir Baldwin Spencer is a companion to the journal of the last journey to Tierra del Fuego on which he died. Both in the journal, and in the letters dealing with his work to his friends and co-workers in anthropology, Spencer reveals the inner working of his mind in its reaction to the subject matter of his research and to the ideas suggested in the comments of his correspondents. The letters selected for publication in this volume begin in 1896, the earliest being addressed to Lorimer Fison; the latest is to Dr. R. R. Marett, being dated April 27, 1929, within a short time of his death. By far the greater number, however, are directed to Sir James Frazer, and the editors, happily, have included those sent to Spencer by Sir James in reply. Among other correspondents are Dr. Henry Balfour and Walter E. Roth.

This record of an exceptional personality will be valued by Spencer's friends; but as a collection the letters are of more than sentimental value. As the correspondence, for example, with Sir James Frazer proceeds, it is possible to note the gradual development of Spencer's grasp of the meaning of the material he had gathered, and the testing and modification of the hypotheses which, in their final form, were to become to the anthropologist as household words. Most instructive of all is the interchange of idea and suggestion between Spencer and Frazer in which an ideal co-operation between field-worker and theorist was maintained through many years.

The Social and Economic Aspects of the Drink Problem. Pp. 180. (London: Victor Gollancz, Ltd., 1931.) 5*s.* net.

THIS is the report of a social and economic committee consisting of Prof. A. L. Bowman, Prof. A. M. Carr-Saunders, Sir James Hamilton, Sir John Mann, Mr. B. Seebohm Rowntree, Mr. Cecil Rowntree, Sir Edgar Sanders, and Mr. F. D. Stuart, the honorary secretary. The only injunction was that the report was to be absolutely free from bias, and no attempt was to be made to stress either the good or the bad qualities of alcohol. We may assume therefore that the conclusions arrived at are impartial. They are very interesting. During recent years there has been a large reduction in the consumption of alcoholic liquor. At the present time and under prevailing conditions, drink is not seriously impairing industrial efficiency. Heavy drinking is most noticeable among the labouring and casual classes. The proportion of income spent on drink is about the same on the average as before the War. The poverty-creating effect of drink is little, if any, less. Drink is the cause of about forty per cent of the more common offences dealt with at the public courts. About fifty per cent of cases of assault and wilful damage are due directly to drink. The contribution of the liquor trade to agriculture does not appear to exceed nine millions a year.

The book makes excellent reading, but the difference of opinion of the various witnesses is so great that it is difficult to assess the true value of much of the conclusions to which we are apt to come.

The Journal of the Institute of Metals. Vol. 49. Edited by G. Shaw Scott. Pp. 416. (London: Institute of Metals, 1932.) 31*s.* 6*d.*

THE subject of corrosion, in one form or another, occupies a prominent place in this volume. The Autumn lecture by Dr. Gough gives the most complete account yet available of corrosion-fatigue, an effect which is found more and more to be responsible for the failure of stressed parts in practice, as the conditions are more carefully studied. It is concluded with much probability that stress as such is not an important factor; it is rather strain which is important, especially in its effect on protective films. A further communication by Gough and Sopwith shows that atmospheric air must be regarded as a corrosive agent in fatigue tests on most metals, so that the standard of reference should not be the fatigue limit in air but *in vacuo*. Other communications deal with accelerated and prolonged corrosion tests and with the artificial production of green patina on copper, an example of corrosion deliberately produced and controlled. The electrolytic production of a coating of basic sulphate is found to give the best results.

The technical side of the manufacture of non-ferrous metals is represented by papers on moulds for strip casting and on hot-rolling, whilst laboratory experiments on the removal of gases from molten metals have an important practical bearing.

The abstracts published by the Institute being now confined to a separate volume, the present volume is composed entirely of original communications.

Constitution-Types in Delinquency: Practical Applications and Bio-physiological Foundations of Kretschmer's Types. By Dr. W. A. Willemse. (International Library of Psychology, Philosophy and Scientific Method.) Pp. viii + 266 + 32 plates. (London: Kegan Paul and Co., Ltd., 1932.) 15*s*. net.

DR. WILLEMSE is lecturer in psychology in the University of Pretoria. He discusses the relation of delinquency to types of constitution, basing his ideas on Kretschmer's well-known work; the reviewer prefers the division into leptosome, pyknic, and athletic. One of the most interesting chapters in the book is the author's discussion of other typological studies, particularly with those of Jaensch with his "B" and "T" types which correspond roughly with the cyclothymes and schizothymes of Kretschmer. He points out the similarity between the athletic type of delinquent and the epileptic personality. Athletics are very subject to outbursts of anger and aggressiveness, which outbursts would appear in some way to be associated with the adrenal cortex, and according to Berman, also with the pituitary and male interstitial glands. The notorious Kürten, judging from his photograph, belongs to the athletic type of criminal; he was a typical epileptoid. The subjects of this study were boys between the ages of 16½ and 21½ years, and were confined in the Junior Adult Reformatory at Tokai, and at Houtpoort.

Altogether this book is most readable and introduces us to a very interesting point of view towards crime and the criminal.

Co-operation in Marketing Dairy Products. Part I: *Aims and Agencies;* Part II: *Price Plans.* By R. W. Bartlett. Pp. x + 299. (Springfield, Ill. and Baltimore, Md.: Charles C. Thomas; London: Baillière, Tindall and Cox, 1931.) 21*s*. net.

THE bent of the American mind is towards a greater degree of systematisation than is evident in Great Britain; if an American can reduce anything whatsoever to rule and line, tabulation and percentages, he is entirely in his element. The present work conveys this impression very strongly, but there is no doubt that the author educes strong arguments in favour of co-operative action regarding dairy-products marketing, whether in the form of fluid milk and cream, or the many manufactured processes. The name "Piggly Wiggly Stores" (p. 52) is entirely trans-Atlantic, nor need English people wish to rival such nomenclature.

Before co-operation could reach its present position, many difficulties had to be encountered and overcome; and though there may be room for improvement, the advance in this direction made by the United States is notable. The many charts, tables, graphs and diagrams aid in the elucidation of an already lucid text. The health programme of the National Dairy Council (pp. 104–105) is worthy of the closest attention. Whilst the care exercised in the preparation of the text is manifest, it may be recommended that in a future edition greater attention shall be devoted to exact and orderly arrangement of the index.

Talking Pictures and Acoustics. By C. M. R. Balbi. Pp. ix + 126. (London: The *Electrical Review*, 1931.) 7*s*. 6*d*.

SUCH an up-to-date subject certainly calls for an up-to-date exposition, and this is provided by Mr. Balbi's treatise, which is lucidly introduced by Sir Oliver Lodge.

In a series of nine chapters are sketched out the various points; and so far as a general reader may be expected to grapple with highly technical terms, the subject is brought within such reader's ken. For the scientific workers in filming, the book should be full of suggestiveness. It is satisfactory to note that the fear that deaf people's chief source of entertainment (the moving picture) would be shelved in the near future by reason of the introduction of the 'talkie', is disproved, as "by by-passing some of the electrical energy through a special form of receiver, the audibility afforded can in general be restored to 100 per cent".

One chapter deals with varieties of recording apparatus, and the next considers the various systems of talking apparatus; the accompaniment of clear diagrams and of other illustrations to a well-selected phraseology proves sufficiently attractive. Chaps. v and vi are more directly concerned with the consideration of acoustical properties, and are followed by brief practical notes upon the provision of the ideal studio and the ideal auditorium.

Influence of the Pacific on the Circulation in the South-West Atlantic Ocean

By A. J. CLOWES, Scientific Staff, "Discovery" Committee

FOR some time the ships of the "Discovery" Investigations have been accumulating hydrographic data in the South-West Atlantic in connexion with whaling research, and it is considered that a preliminary account of some of the principal features would be of interest.

The surface water of this area is divided into two main types by two distinct convergence lines. The more southern of these has been named the Ocean Polar Front by Defant[1] and is called by us the Antarctic Convergence, while the more northern is called the sub-Tropical Convergence. Both Defant and Wüst[2] base the position of the Antarctic Convergence on a chart of the surface currents by Meyer, who places it at approximately 50° S. between 45° W. and 5° E., but between 40° W. and 60° W. it is considered that it forms the boundary between the Falkland and the Brazilian currents in about 40° S. Our intensive work in the South-West Atlantic shows, however, that this boundary is part of the sub-Tropical Convergence, and that the Antarctic Convergence is found in 58° 50′ S. south of Cape Horn, and that it continues to the north-east, being found in 49° 50′ S. at 40° W.

The waters of the South-West Atlantic may be summarised as consisting of a surface layer of either antarctic water (in the antarctic zone of the ocean) or of sub-antarctic water (in the sub-antarctic zone), below which is found an intermediate layer of relatively warmer and more saline water above the bottom layer, the Antarctic Bottom water. Wüst agrees with Merz that the intermediate layer of warmer and more saline water is of North Atlantic origin; he also states: "Just as Merz could trace the last vestiges of this water (*N. Atlantic Deep water*) as far as about 65° S. in the observations of Brennecke, so in the east the 'Meteor's' observations place the furthermost limit at 56° S."

The Atlantic Ocean is separated from the Pacific Ocean by the Drake Passage of approximately 450 miles, between South America and the northernmost point of Antarctica at Graham Land. The question arises, What influence has the Pacific on the circulation and composition of the water in the South-West Atlantic? Wüst states that the influence of the Pacific Ocean is of secondary importance. However, our data quickly showed that there is a considerable eastward flow through the Drake Passage on both sides of the Antarctic Convergence. Moreover, this flow is not confined to the surface layer only but is continuous to the very great depths of the Drake Passage. Thus no water of Atlantic origin passes into the Pacific. Lack of space precludes the reproduction of many diagrams, but the topographical chart for the 600 decibar surface in relation to the 3,000 decibar surface is given in Fig. 1. The chart is constructed by making use of the observed densities at 72 stations of which the greater part lie in the Scotia Sea, and gives the stream lines of the currents at the level indicated, assuming the velocity at 3,000 metres is zero, or so small that it does not affect the magnitude of currents at lesser depths. The level of 600 metres has been chosen because in the region of South Georgia the maximum temperature of the intermediate warm and more saline water occurs at 600 metres.

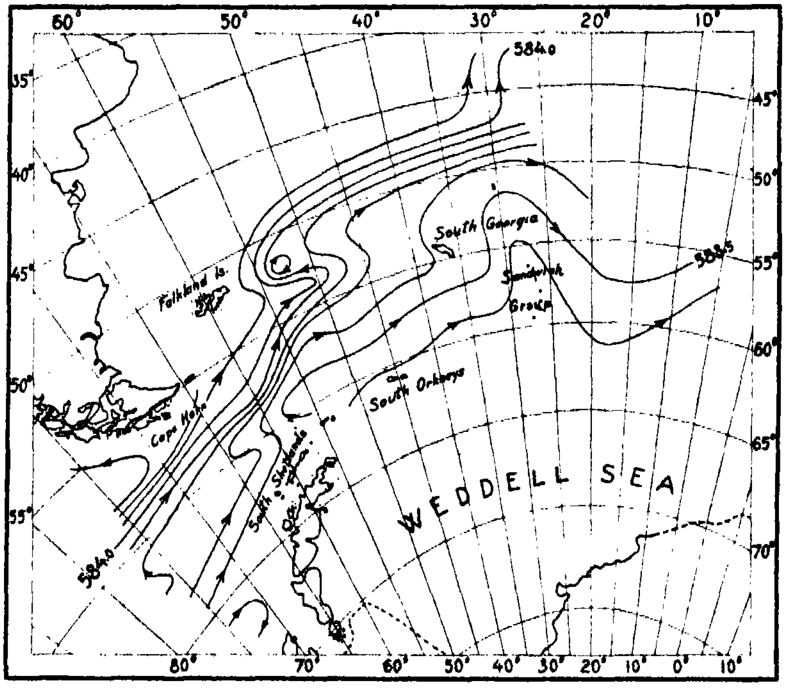

FIG. 1. The currents at 600 metres relative to the currents at 3,000 metres. The lines show the topography of the 600 decibar surface relative to the 3,000 decibar surface.

It can be seen from this chart that the water flows from the Pacific through the Drake Passage in a north-eastwards direction into the Atlantic, and continues northwards of South Georgia. The great bends of the dynamic isobaths in Fig. 1 between South Georgia and the Falkland Islands, between the South Sandwich Islands and South Georgia, and close to Graham Land are characteristic and permanent features and are related to the topography of the sea bottom, but several details may be due to the circumstance that observations from different years and seasons have been combined. At the 2,000 metres level the water flows in the same direction as at 600 metres, but the velocities are much smaller. Thus the maximum velocity at 600 metres is about 32 cm./sec. but at 2,000 metres it is about 8 cm./sec.

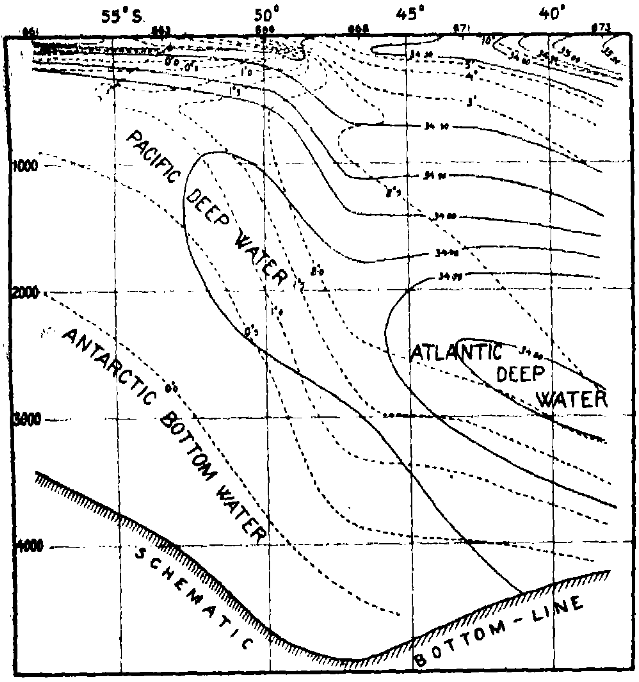

FIG. 2. Vertical section of salinity and temperature along 30° W. from 57½° S. to 48° S.

Fig. 2 is the vertical section of salinity and temperature along long. 30° W. At Station 666, the water of temperature between 1·99° and 1·02° and salinity between 34·62 and 34·73 per mille would have originated in the North Atlantic according to the conception of Wüst, whereas according to our view it came from the Pacific. It has been found by Helland-Hansen that there is a very distinct relationship between temperature and salinity of sea water. Briefly, it may be stated that water masses possessing the same temperature and salinity have a common origin. Thus if we examine the graphs of the relationship between temperature and salinity for a station in the Drake Passage and one or two north of South Georgia, it will be possible to determine the correctness of our view of the water movements in this area. In Fig. 3 the temperature-salinity diagrams for depths below 100 metres have been drawn for three stations, Station 647 in the Drake Passage, and Stations 666 and 671 both north of South Georgia. The agreement between the curves for Stations 647 and 666 is excellent, whereas there is a striking disagreement between the curves for the two former stations and that for 671. Only at depths below 2,000 metres is the water at 666 similar to that at 671 below 3,500 metres, thus showing the common influence of the Antarctic Bottom water from the Weddell Sea at both stations.

Thus the temperature-salinity diagrams agree with the topographical charts that the warm, more saline intermediate layer in the South-West Atlantic originates in the Pacific. It is only north of 46° S. that the deep water shows a southerly component and is of Atlantic origin; south of 46° S. it is of Pacific origin as far as about 55° S., where the influence of the Weddell Sea is predominant.

On the basis of the sections through the Drake Passage, it is possible to compute the total volume of water which flows from the Pacific to the Atlantic, assuming that the velocity is zero at a depth of 3,500 metres. Using data from two different years, 1929 and 1930, one finds nearly the same values, namely a transport of about 110 million cubic metres a second. This transport is more than four times as great as the total flow of water through the Strait of Florida. Considering water of a salinity of more than 34·65 per mille as Pacific deep water, one finds that more than one third of the water which flows through the Drake Passage is of this type, and it is evident that such a tremendous inflow of Pacific deep water to the Atlantic must have an appreciable influence on the character of the water masses in the southern part of the western Atlantic. There it is met with as an intermediate layer between the light surface water and the heavy Antarctic Bottom water.

In conclusion, it is of interest to consider the circulation of the Southern Ocean as a whole. All around the antarctic continent there exists one continuous current, flowing from west to east. Within the upper layer of this current one can discriminate between two typically different water masses, the antarctic water, and the sub-antarctic water of the west wind drift. These two water masses are separated by a boundary surface which

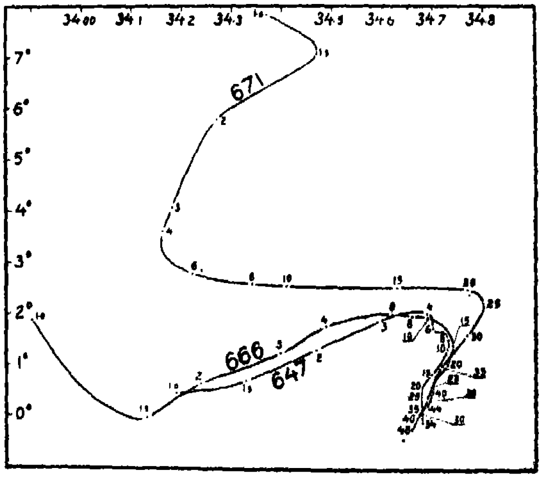

FIG. 3. Diagram of the relation of temperature and salinity for Stations 647 (58° 29¼′ S., 58° 39¼′ W.), 666 (49° 58½′ S., 29° 52¼′ W.), 671 (48° 08′ S., 30° 15½′ W.). The numbers alongside the curves represent the depths of the observations in hectometres.

at sea level is recognized as the line of Antarctic Convergence. To the south of the broad easterly current a series of whirls are probably formed. These circular movements, of which the greatest is found in the Weddell Sea, are stationary and dependent upon the topographic features of the bottom of the sea, and of the coast line of the antarctic continent. In the regions of these whirls the places have to be sought where the Antarctic Bottom water is formed. To the north of the easterly current one finds the sub-Tropical Convergence representing the boundary between the warm and saline water from the Atlantic or Indian Oceans and the sub-antarctic water. Along this boundary surface, whirls are probably also developed, but these are not stationary but represent travelling disturbances which uphold processes of mixing. Through this mixing, the character of the eastward-flowing water slowly changes. The water in 65° S. and approximately 28° W., which Merz and Wüst have considered as being of Atlantic origin, belongs according to our view to the great whirl of the Weddell Sea, which, however, represents a closed system to the south of the current from the Pacific, and therefore the warm and saline intermediate water of the Weddell Sea is for the most part of Pacific and not of Atlantic origin. The so-called Indian Ocean intermediate warm and saline water found in the southern part of the Weddell Sea is no doubt typical water of the circumpolar system.

I have had the advantage of discussing these results with Dr. H. U. Sverdrup, to whom I wish to express my grateful thanks.

Helium Liquefaction Plant at the Clarendon Laboratory, Oxford

By Prof. F. A. LINDEMANN, F.R.S., and T. C. KEELEY

THE main properties of liquid helium have been familiar to men of science for a great many years. The only object therefore in liquefying it is in order to cool other substances the characteristics of which it is desired to study in the neighbourhood of the absolute zero. It has long been known that the heat capacity of solids becomes extremely small at low temperatures. Thus the latent heat of evaporation of 20 mgm. of liquid helium is sufficient to cool 60 gm. of copper from the temperature to be attained with liquid hydrogen boiling under a reduced pressure to the boiling point of helium.

It is easy to design apparatus so that the substances the properties of which at low temperatures are under investigation, are cooled to the temperature of the surrounding liquid or solid helium and maintained at this temperature with a minimum of waste. It seemed preferable, therefore, to instal a small inexpensive apparatus requiring comparatively little liquid hydrogen, which can therefore be operated frequently or duplicated at comparatively small cost, rather than to indulge in a plant designed to produce liquid helium in large quantities. In any event, the financial resources available would have imposed this choice, even had the alternative procedure been considered desirable.

The apparatus which has been installed at Oxford is of a type developed by Prof. Simon and Dr. Mendelssohn in Berlin and Breslau. Two concentric cylinders capable of withstanding a pressure of some 150 atmospheres surround the space in which the substance under investigation is placed. Helium under a pressure of about 100 atmospheres is introduced into the space between the cylinders. The upper part of the annular space between the cylinders is separated from the lower, in which the helium is compressed, by a metal sheet, thus forming a small metal container which is joined by a spiral of thin copper tubing to a source of pure hydrogen. The whole is held in position on a German silver tube in the centre of a larger metal vessel containing hydrogen or helium gas at low pressure which can be evacuated by means of a mercury vapour pump. This outer vessel together with the copper spirals through which the hydrogen and helium are introduced is immersed in a Dewar flask containing liquid hydrogen.

When temperature equilibrium has been attained, hydrogen is introduced into the top vessel under a pressure of two or three atmospheres. Passing through the copper spirals, this liquefies owing to the excess pressure and runs down into the metal container over the double-walled helium cylinder. A tap to the mercury vapour pump is now turned on and a high vacuum produced in the metal box, so that the helium container with its superposed pot of liquid hydrogen is thermally insulated save for the necessary connecting tubes.

The yield of liquid helium is improved if the compressed helium is further cooled by boiling the hydrogen in the inner container under reduced pressure. If the helium is now allowed to expand, about half of it liquefies and the central space with the experimental substances it contains is cooled to the temperature of the surrounding helium. By evacuating the space above the liquid, that is, causing it to boil under reduced pressure, one can, of course, reduce the temperature to within one or two degrees of the absolute zero.

In the apparatus used at Oxford the helium lasts for about an hour and a half. If the experiment is not finished in this time, one can repeat the process in a few minutes at very small cost in liquid hydrogen. The helium expands into a rubber bag and is recompressed into a cylinder so that very little gas is lost. The temperature during the experiment can be observed on a large-scale manometer connected through a fine tube to a small vessel containing helium in the liquefaction space. The apparatus cost approximately £30. Since there is no need to recompress the helium rapidly, a small cheap compressor is sufficient.

The liquid hydrogen required is produced in a plant of the standard pattern designed in the Physico-Chemical Institute in Berlin which has been in use at Oxford for some years now without giving any trouble. Impurities in the hydrogen are condensed by a preliminary expansion and continuously removed by a slow stream of hydrogen. With a compressor capable of dealing with ten cubic metres of free gas an hour and an expenditure of approximately 1·4 litres of liquid nitrogen per litre of liquid hydrogen, this plant produces some 2½ litres of liquid hydrogen per hour. Liquefier and compressor together cost approximately £350.

The liquid hydrogen is stored in pyrex Dewar flasks silvered and exhausted in the laboratory. As their efficiency equalled that claimed for the more complicated double vessels developed by Prof. Kapitza, they have been retained.

If low temperature work expands and a large number of experiments are in hand simultaneously, it may be necessary to consider the use of the continuous Linde process of liquefaction. In view of the cost of the gas and the precautions necessary for its recovery, its distribution involves considerable inconvenience, which for the time being are scarcely worth facing. The mere liquefaction, of course, offers no difficulties and there is little doubt that the Berlin type of apparatus, which is already in use in many laboratories, will prove as serviceable and efficient as the hydrogen liquefier, should it ever be necessary to change over to this system.

Finally, a word of thanks is due to Dr. Mendelssohn, who kindly brought the liquefier over from Breslau and placed all his knowledge and experience unreservedly at the disposal of the department. But for this, it would scarcely have been possible to obtain, without hitch or trouble, liquid helium within one week of the arrival of the apparatus in Oxford.

Metrology by Light Waves at the National Physical Laboratory*

IN 1923 the International Committee of Weights and Measures accepted the eventual use of a wave-length of light as the ultimate standard of length. Already in the previous year the Board of Trade had recognised the need of replacing the existing Imperial standard yard by a standard more in accord with modern requirements. For these reasons it was decided that the National Physical Laboratory should establish means of realising a wave-length standard of length and with it determine the length of the Imperial standard yard in terms of that wave-length.

The paper cited below, by Messrs. J. E. Sears, Jr., and H. Barrell, gives an account of the apparatus and methods which complete the first stage of this programme.

The new apparatus is of the type used by Benoît, Fabry and Perot, but is distinguished from the two previously existing instruments of this type in very many features of design. The more important new characteristics of the apparatus result from two radical departures from what was aimed at in the earlier instruments.

In the first place, Benoît, Fabry and Perot compared their optically determined metre etalon with a line standard by the usual methods of microscope observations, with the aid of fine lines scribed on the polished edges of the terminal glass plates of the metre etalon; the prototype metre being a line standard, such procedure was unavoidable at some stage of the work. In contradistinction to this, the apparatus at the National Physical Laboratory derives the length of an end standard directly from the length of the metre etalon by optical interference, the ends of the etalon being polished parallel to a high optical precision by the Pitter Gauge and Precision Tool Co. of Woolwich by a technique worked out at the Laboratory in 1920. This procedure avoids one of the most difficult steps in the earlier work—the correlation of the positions of the reflecting surfaces of the metre etalon with those of the graduation lines.

Secondly, the new apparatus is so designed that measurements may be made either in air under controlled conditions, or in vacuum, and it thus makes possible new determinations of the refractive index of the air under various atmospheric conditions, which in any event will be needed before a wave-length definition of unit of length can be finally adopted for measurements of the highest precision. Measurements of this kind involve the observation of such variable factors as temperature, barometric pressure, humidity and possibly even carbon dioxide content of the air, and there are disagreements among the published values of the effects of these factors on the refractive index of the air.

It may be also noted here that the separation of the plates in the etalon which is used for the initial measurement has been increased from the 1/16 m. used in the two earlier instruments to 1/12 m., thereby leading to a greater relative accuracy in the basic measurement.

Although the above-mentioned new features of design are in principle the most important, those interested in the design of instruments will perhaps derive most pleasure in considering other details. The apparatus is characterised by a full envisagement of what functions were to be carried out and an adequate provision of means for their convenient and certain execution: one gets the impression that in using the apparatus there will be no need for successive trials in order that an essential adjustment or observation may be secured. Two examples of this must suffice.

---

* "A New Apparatus for Determining the Relationship Between Wave-Lengths of Light and the Fundamental Standards of Length", by J. E. Sears and H. Barrell, *Phil. Trans. Roy. Soc.*, A, vol. 231, pp. 75–145. Sept. 16, 1932.

One of the difficulties in the construction of etalons for such an apparatus is in securing that the lengths are exact multiples of the shortest one. Instead of relying on trial and error polishing of the ends, the etalons at the National Physical Laboratory are adjusted by four strain wires symmetrically disposed around the etalon, by means of which changes in length of any etalon of so much as 1 part of 25,000 can with certainty be produced without exceeding the elastic limit of the strain wires.

Again, not only must the supporting mechanism of the longest etalon be capable of the very accurate parallel displacements which are necessary, but such displacements must also be made with certainty and convenience and without varying the distribution of load on the supporting pillar and so forth. The means whereby this manipulation is secured are worthy of special attention.

It is a matter for great satisfaction that the Board of Trade together with the National Physical Laboratory decided to place metrology in the British Empire on a wave-length basis; and the designers and the workshop personnel of the National Physical Laboratory are to be congratulated on the successful completion of the first part of the programme.

Obituary

LIEUT.-COL. J. STEPHENSON, C.I.E., F.R.S.

We regret to announce the death, which occurred in London on February 2, of Lieut.-Col. John Stephenson. He was born in 1871 at Padiham, Lancashire, and was educated at the Burnley Grammar School and the University of Manchester, where he had a distinguished career as a student in science and in medicine. After graduating, he acted as house-surgeon in the Manchester Royal Infirmary and in the London Hospital for Diseases of the Chest. In 1895 he was appointed to the Indian Medical Service and for the next five years was on military duty, including service in the North West Frontier Expedition of 1897. During the following years he was on plague duty and held various appointments as civil surgeon in the Punjab until in 1906 he became professor of biology in Government College, Lahore, of which he was appointed principal in 1912.

In Manchester, Stephenson had studied zoology for two years under the stimulating influence of Prof. Milnes Marshall, and with this foundation he instituted in Lahore instruction in the subject which reached a high standard and within a few years resulted in a productive school of zoology. Several of the students from his laboratories, whom he inspired with his own ideals of critical work and with the need for the investigation of the fauna of their country, are now holding influential zoological posts in India and have published important papers on their researches. His tenure of office in Lahore was marked by conspicuous success as a teacher and by high administrative qualities, and his quiet, effective personality left a deep and lasting impression on his students.

Stephenson resigned his post in Lahore in 1920 and I was fortunate in being able to attract him to the University of Edinburgh, in which he was appointed lecturer in zoology, to share in conducting the courses on invertebrates for senior students. His teaching was clear and concise, with a wide scientific outlook, and he was unsparing in giving help and encouragement, especially to those who were reading for honours in zoology. In Lahore, immediately after taking up his duties, Stephenson began investigations on the aquatic oligochætes of the Punjab and during the next ten years published a series of papers on these worms. His interests then widened to the oligochætes in general and he examined numerous collections from various parts of India. These studies were continued with great assiduity in Edinburgh and in 1923 he published the important volume on the oligochætes in "The Fauna of British India" and became recognised as one of the two chief authorities on the order. Before he resigned his lectureship in Edinburgh in 1929, he completed the masterly monograph on the Oligochæta which was published early in 1930 by the Clarendon Press. Stephenson's mastery of the structure and classification of oligochætes, his extensive knowledge of the literature and his flair for conciseness and clearness in presenting facts and conclusions, enabled him to produce a monograph of exceptional merit which contains also conclusions of general interest; for example, on the bearing of the known facts of geographical distribution on the former existence of a more extensive antarctic continent and of Indo-Australian and other land-bridges, on convergence and on polyphyly. Stephenson was appointed in 1928 editor of "The Fauna of British India" in succession to the late Sir Arthur Shipley.

On leaving Edinburgh in November, 1929, Stephenson went to reside in London and continued his investigations on oligochætes as an unofficial worker in the Natural History Museum until about two months ago. Two years ago he became zoological secretary of the Linnean Society and took an active part in its affairs.

Stephenson was the author during the last twenty-seven years of numerous papers on Oligochæta. His contributions to the advancement of knowledge were recognised by the award in 1920 of the Keith Medal of the Royal Society of

Edinburgh and by his election in 1930 as a fellow of the Royal Society of London.

Stephenson regarded as a recreation his studies, which were carried out with his usual thoroughness and care, in Persian and Arabic history and literature. He published the text, with translation, and with commentary or annotations, of two works, the second of which (Royal Asiatic Society, 1928), the zoological section of the Nuzhatu-*l*-Qulūb ("Heart's Delight") was compiled by a Persian author about the year 1340 and gave a conspectus of zoological science of the time.

Col. Stephenson was held in high esteem as a sincere and loyal friend, for his sound judgment and for his readiness to help in all matters relating to the advancement of zoology in Great Britain and in India. His many friends will feel a deep sense of personal bereavement and will extend their sincere sympathy to Mrs. Stephenson.

J. H. ASHWORTH.

DR. JOHN THOMAS

JOHN THOMAS was born at Harlech in 1886 and died at his home at Wilmslow, Cheshire, on January 18, 1933. He obtained a scholarship at Barmouth County School as a boy and afterwards became a science student at University College, Aberystwyth; he entered at Trinity College, Cambridge, in 1908 with an 1851 Exhibition and, after taking his degree in 1910, was awarded a post-graduate research exhibition by the College.

Thomas soon showed notable talents as an organic chemist and published several papers on this subject while at Aberystwyth and Cambridge. In 1911 he joined the aeronautical section of the National Physical Laboratory as a research chemist and in the following year took up a similar position on the staff of the Nobel Explosives Co. at Ardeer. While at Ardeer he distinguished himself by investigations on novel and delicate explosive compounds which came into prominence during the War; his original experimental work on these and other subjects gained for him the degree of D.Sc. of the University of Wales.

In 1918, Thomas became chief chemist to the Solvay Dyes Co. which had just been founded by Mr. James Morton at Carlisle for the manufacture of fast dyes of the indanthrone group; these important essentials of the textile industry had not previously been made on a technical scale in Great Britain. When the original company was reconstituted as Scottish Dyes, Ltd., Thomas was appointed a director and soon after, in 1923, became the managing director. The manufacture of the fast vat dyes involved the translation of a delicate laboratory technique into large scale practise and for this work Thomas, as a skilful experimenter gifted with marked originality and breadth of view, was eminently suited. During the succeeding years, Thomas's name was attached to numerous patents for the preparation of new and improved vat colours and, as a result, the great works which Dr. Morton established at Grangemouth on the Firth of Forth, now competes on equal terms with the German and Swiss producers of vat dyes. Scottish Dyes, Ltd., was absorbed by the British Dyestuffs Corporation and Imperial Chemical Industries, Ltd., in 1926; in due course, Thomas became joint managing director of the Dyestuffs Group of the latter organisation and held this position until the end.

Thomas was a master of his subject and combined with his experimental genius a fertility in expedient and an aptitude for organisation which are altogether rare; he was a happy and charming personality and a delightful companion. By his untimely death at the age of forty-six years the chemical industry has lost an outstanding figure and many of us have lost a very dear friend.

W. J. P.

MR. C. M. STUART

CHARLES MADDOCK STUART was a member of a large family with a remarkable record of strenuous endeavour combined with religious fervour and a roving disposition; one of his brothers was Canon of Canterbury, the recently deceased Dean of Carlisle was another; the late James Stuart, so well known at Cambridge, founder of the Mechanical School now the School of Engineering, was their cousin. I have briefly set out the family history, in an article in the February number of the *Journal of Education*, as an outstanding example of family heredity.

Stuart was born on September 25, 1857; he died on November 22, 1932. He was educated at Harrow and then entered St. John's College, Cambridge, of which later on he was a fellow. He paid attention chiefly to chemistry and took a first in the Natural Science Tripos in 1880. He next studied with Fittig at Strasbourg. Returning to England, he was first a master at Clifton College, afterwards at Newcastle-under-Lyne under Kitchener; finally, in 1888, he became headmaster of St. Dunstan's College, Catford, S.E., then opened as a new school. He thus came into my neighbourhood and we were close friends from the beginning up to his death. My four sons were educated at the school. Prof. Andrade was one of his pupils; Oscar Faber, the engineer-architect of the new buildings of the Bank of England, was another; Mees and Sheppard, of photographic note, in connexion with the Kodak Co., were also trained at the school. The numbers rapidly rose to five hundred and the school soon became far the best in the Metropolitan area, probably in the country.

He was a keen mountaineer and a man of great physical vigour, as much at home with his boys at cricket and lacrosse as in the class rooms. He was an experimentalist from the beginning, greatly influenced by the exact training he had from Fittig. He is the only head-master I have known who acted as master of method throughout his school: every subject gained through his inspiration. His desire was to make his school suit modern needs. Had the material at his disposal been of a higher mentality, he might have achieved startling results. In a brief note in the *Times* (Nov. 28, 1932) I have ranked him above Sanderson of Oundle, who was trained as a theologian and as an engineer and first became known at the nearby school, Dulwich College, where he established an engineering department, the first of its kind. Comparing the manual work in the two schools, St. Dunstan's was undoubtedly the better, without show and really disciplinary. Sanderson soon became a visionary and cultivated the spectacular: Stuart was to remain a reticent, unassuming Scot; he was almost a Cromwellian puritan in general outlook, without a trace of the cleric and yet a man of great moral force. He put his day school upon as high a moral and social level as that of any public boarding school: this was his great work. He believed in the sympathetic constructive inspector but hated examinations in every shape and form; he did not even accept them as necessary evils; he saw that they made all progress in methods of teaching impossible.

Schools of the type Stuart created are, I believe, the schools of the future. Men of his type will be the future head-masters, if they can be found and provided with proper assistance. Unfortunately we have not yet discovered how to maintain a school when once established—comes a new head and it at once changes. We will not learn from one another; only those who cannot lead will follow a leader. H. E. A.

WE regret to announce the following deaths:

Prof. Eugen Bamberger, emeritus professor of general chemistry in the Technische Hochschule at Zurich, who carried out numerous investigations, chiefly on aromatic and heterocyclic compounds, aged seventy-five years.

Dr. Alfred Eichholz, C.B.E., chief medical inspector, Board of Education, on February 6, aged sixty-three years.

Sir Frederic G. Hallett, O.B.E., formerly secretary of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons, on February 5, aged seventy-two years.

Dr. H. Theodor Holm, known for his work on arctic botany and on plant anatomy, on December 26, aged seventy-eight years.

Prof. E. H. Moore, emeritus professor of mathematics of the University of Chicago, president in 1921 of Section A of the American Association, who was known for his work on the theory of numbers, on December 30, aged seventy years.

Prof. A. H. Sayce, formerly professor of Assyriology in the University of Oxford, on February 4, aged eighty-seven years.

Prof. Alfred Schaarschmidt, president of the Institute of Chemical Technology at the Technische Hochschule, Charlottenburg, who was specially interested in problems of nitration, aged forty-nine years.

Sir William Taylor, K.B.E., regius professor of surgery at Trinity College, Dublin, president of the Royal Academy of Medicine, Ireland, since 1927 and president of the Royal College of Surgeons, Ireland, in 1916, on January 29, aged sixty-one years.

News and Views

Award of the Duddell Medal of the Physical Society

THE council of the Physical Society has awarded the tenth Duddell medal to Prof. Wolfgang Gaede, director of the Physical Institute at Karlsruhe, and until recently professor of physics at the Technische Hochschule there. Prof. Gaede's name will always be associated with the design and production of high vacuum pumps. Before 1905 the production of a vacuum beyond that attainable with a filter pump or piston pump was a tedious operation, carried out almost always with a mercury pump of the Toepler or Sprengel type. The remarkable thing about Gaede's investigations is not merely that at the age of twenty-seven he designed a rotary mercury pump which was simple, easy to work, and marked a great advance, but also that since then he has produced at intervals a number of vacuum pumps, each with a definite field of utility, and some of which are based on wholly new principles developed largely by Gaede himself. Thus the rotary mercury pump of 1905 (for many years the pump chiefly used in electric lamp manufacture) and the rotary oil pump of 1907 were followed in 1913 by the rotary box pump used as a backing pump for high vacuum pumps, and by the molecular air pump, which was the first of the really high-speed pumps. In 1915 came the mercury vapour diffusion pump, the forerunner of nearly all the high-speed vacuum pumps used to-day, whether employing oil or mercury vapour. Within the last ten years, Gaede has designed a family of pumps of several stages, incorporating both the high-vacuum and the fore-vacuum pump into a single unit. A recent outstanding development was the large single-stage diffusion pump designed by Gaede for work at Leyden on solid helium. This had the remarkable speed of several hundred litres per second at a pressure of 1/1000 mm. mercury.

White and Black in Africa

SOME essential factors in the problems affecting the future of the white and black races in Africa were indicated by Mr. Frank H. Melland, formerly of the administrative service of Northern Rhodesia, in a lecture on "Witchcraft in Africa" before the African Society on January 31, at which Lord Buxton was in the chair. Mr. Melland pointed out that while the native visits the white man on a friendly basis and brings certain of his troubles to him, this does not apply to witchcraft, because the white man does not believe in it. The problem is to teach the black man to think 'white', just as we ourselves in many parts of Africa are trying to think 'black'. Hence Mr. Melland stressed the value as an educative influence of carefully selected films of British life which should be brought before the native. While it is perfectly obvious that as the conditions of life and hygiene in tropical Africa become better understood, the number of white settlers will increase, it is frequently overlooked that the black man is equally a permanent element in the future situation which must be taken into account. As Mr. Melland pointed out, he will not disappear as the red man in America or the Australian blackfellow have disappeared, nor will he survive as an historical curiosity. The Bantu are the most virile and persistent racial stock extant, and they outnumber the white man in the highlands of Africa by fourteen to one. Lord Buxton, judging from his own experience, thinks that the belief in witchcraft is by no means so strong as it was some years ago; but taking this as symptomatic of advance in other directions, progress must be slow. If it were not for difficulties of which there has been abundant evidence recently, it would seem scarcely necessary to urge the necessity for the scientific study of native ways of thought and institutions to ensure that progress in native development is in a direction which will permit of the two races living side by side in one community, as forecast by Mr. Melland.

Aims of Anthropological Research

PROF. FRANZ BOAS of Columbia University, in his presidential address to the American Association for the Advancement of Science at the meeting at Atlantic City in December last, made a survey of present-day methods of approach in anthropological research, which was remarkable not only for the thoroughness with which it traversed the ground, but also for the critical acumen which probed weak spots in the theories dominant at the moment in the various schools of thought. He suggested caution in estimating the possibilities of formulating general laws. His final conclusion is that the study of 'foreign cultures' should enable us to see how many of our lines of behaviour, that we believe to be founded deep in human nature, are actually expressions of our culture and subject to modification with changing culture. "By a study of the universality and variety of cultures," he said, "anthropology may help us to shape the future course of mankind." Prof. Boas, holding that the objective of anthropology is the attempt to understand the steps by which man has come to be what he is biologically, psychologically and culturally, also holds that its material must be historical in the widest sense of the term, and that in the argument for diffusion it is not a safe method to assume that all analogous cultural phenomena must be related. "It is necessary," he says, "to demand in every case proof of the historical relation, which should be the more rigid the less evidence there is of actual recent or early contact." Prof. Boas's address appears in full in *Science* for December 30, pp. 605–613.

Dr. John Roebuck, F.R.S., 1718–94

WE learn with interest that the tomb of Dr. J. Roebuck, one of the founders of the famous Carron Iron Works, Falkirk, has recently been restored. Roebuck was born in Sheffield in 1718 and after studying in Edinburgh took the degree of M.D. at Leyden. Returning home, he practised in Birmingham, but, becoming interested in practical chemistry, he was successful in introducing the use of lead chambers into the manufacture of sulphuric acid. In 1759, with Samuel Garbett and William Cadell, he founded the Carron Company, the first concern in Scotland to use coal for smelting iron and the first to use ironstone from the carboniferous formation of central Scotland. Roebuck was the friend of Watt, Boulton, Smeaton and Black, and was a fellow of the Royal Societies of London and Edinburgh. He died in July 1794 at Bo'ness, near Grangemouth, and was buried in Carriden churchyard. His grave is surrounded by a low wall while at the head of it is a marble tablet bearing a long inscription in Greek and Latin, referring to his studies in chemistry and metallurgy, which sciences "he expounded and adapted to human needs with a wonderful fertility of genius and a high degree of painstaking labour". The restoration of the tomb has been carried out by the descendants of Dr. Roebuck and the Carron Company. The Company, it may be added, has published an interesting series of leaflets recalling some of the famous men who have been associated with the works.

Lancaster Frankland Society

AT a meeting held in the Storey Institute, Lancaster, on January 18—the anniversary of the birth of Sir Edward Frankland in 1825—a proposal was brought forward to form a society in Lancaster to perpetuate the memory of this great chemist. Prof. H. E. Armstrong, Frankland's oldest living pupil, in the course of an interesting address, reported in the *Lancaster Observer* of January 20, lent his support to the proposal. Frankland, he said, went to Lancaster at a very early age and remained until 1845, attending first a private school and afterwards the Royal Grammar School; a valuable part of his training was obtained also during his apprenticeship in a local druggist's shop, for there he learnt to use his hands. Prof. Armstrong expressed the hope that the founders of the organisation would remember Frankland not only as a chemist but also as a man of wide attainments, and that besides chemists they would include botanists, geologists, and particularly sanitarians—for Frankland's important work in giving Great Britain a pure water supply lay in association with sanitary science. In supporting the proposal, Dr. Shackleton Bailey mentioned various past pupils of the Royal Grammar School, Lancaster, who have achieved eminence in science, among them being Sir Edward Frankland in chemistry, Sir Richard Owen in biology, Prof. Seward in botany, and Prof. Marr in geology. A letter of support was read from Prof. P. F. Frankland. Prof. Armstrong is to be president of the new society, which, it has been decided, shall be called the Lancaster Frankland Chemical Society.

Biology's Message for Civilisation

IN an address to Sections D and F of the South African Association for the Advancement of Science in July 1932, Prof. H. B. Fantham, recently elected to the chair of zoology in McGill University, Montreal, essayed to interpret biology's message for the plight of modern civilisation (*South African J. Sci.*, vol. 29, p. 533). Prof. Fantham regards the expenditure on education as excessive, and the subjects taught too many; his own ideal list includes general elementary science (including biology), the languages of the country, reading, writing, arithmetic, economic and human geography, history, some cultural subject like singing, needlework and cookery for girls, drawing and woodwork for boys, moral principles, and perhaps simple drill, anything beyond these to be paid for by the parents concerned. Elementary education alone should be free, for so-called free education is 'free' only to the parents directly concerned and not to the community. The mechanisation of the modern world is a disharmony, which is narrowing and starving human life. Doles are "perhaps the greatest biological mistake in the social organisation of the present age"; relief should be made conditional on the giving of service. Generally, Prof. Fantham holds that there is too much administration, too much organisation, too many conferences and too much mechanisation, so that man's environment has become too artificial, and the result of the disharmony is expressed in instability and unrest. Some suggestions made by the author are that government must be by paid business managers trained in science and administration; that production must be adjusted to demand and the scientific organisation of distribution; that wages should be judged by their purchasing power; that the movement back to the land should be encouraged; that wars should cease and war debts be cancelled; and that eugenic measures should be employed to cope with problems of over-population.

The Language Difficulty and Scientific Progress

DURING the course of a year we receive many journals, reports of congresses, and papers printed in languages which, it must be admitted, are unfamiliar to the majority of scientific workers and sometimes in alphabets which add to the difficulties of interpretation. Fortunately, the custom is growing of adding to each paper a summary of its contents in English, French or German, but no summary can ever replace, for a scientific worker, the detail of the method and observations of the paper summarised. The relegating to comparative obscurity, on account of the language difficulty, of many papers of value is all against the progress of scientific knowledge, and it is for that reason that we venture to appeal again for an increased use, if not in whole at least in summary, of the languages which have come to be recognised as the general vehicle of scientific researches. The tendency of recent times was the subject of discussion at the fifteenth annual meeting of the American Society of Ichthyologists and Herpetologists in Washington, D.C., in May 1932, and the following resolution was passed unanimously: "Whereas, a large number of ichthyologists and herpetologists of countries using non-Latin alphabets are publishing their papers in the English language; therefore, be it resolved that the American ichthyologists and herpetologists, through their Society, desire to thank their fellow scientists of other lands for publishing in English."

Use of the English Language

AT the Friday evening discourse at the Royal Institution on February 3, Dr. Cyril Norwood discussed the use of the English language. Dr. Norwood directed attention to the particular dangers to present-day writers arising from the rapid wear and tear of words and phrases, and the decay of metaphors, and pointed out that these arise from, among other things, the excessive use of technical language which reduces words to a system of symbols. Illustrations from the works of leader writers and of men of science were given to show the kinds of error which are very frequent, and to illustrate methods of style which delay the reader's apprehension and defeat the writer's object. The methods of Darwin, who was without natural gifts of style, but took infinite pains to render his writing clear and attractive, were examined and Dr. Norwood suggested that Darwin's example could well be followed. A similar study of Huxley was made, and Dr. Norwood quoted a passage from his writings which he considers is a model of written English.

Economic Value of Agricultural Science

THERE must be few engaged in research who have not been called upon to justify the policy of scientific examination of technical problems in face of the apathy or distrust of the practical man. This is particularly so in the case of agriculture, in which it is still possible to continue by the use of traditional methods. Fortunately, the list of scientific achievements which have given the cultivator vastly greater command over the forces of Nature is a long one; and the critic may be made to realise that practically the whole agricultural technique that was not possessed by his grandfather is the direct outcome of scientific research. In an address delivered to the Wellington Philosophical Society on October 26, Lord Bledisloe, Governor General of New Zealand, very ably sets out the economic value of agricultural science. Addressing his remarks to the primary producer, Lord Bledisloe points out that only by fostering scientific research and applying its results to practice can a place be maintained in world markets, continually more congested and more exacting in their requirements. Research, however, must be thorough, tested out in all its bearings, and put before farmers as a sound investment. Surveying the whole agricultural field, the leading achievements of agricultural research which have led to definite economic results are touched on, and even to those familiar with the subject the cumulative result is impressive. The problem of production has been solved. The famines predicted from time to time in the recent past are not likely to trouble us. The need for the future is to get into wider circulation the plenty which improved methods have secured.

Gold and Silver Currencies

IN a recent publication ("'Standard Gold' and Silver: the Way out of the Crisis." Pp. 88. Manchester: Taylor Garnett Evans and Co., Ltd., 1932), Dr. Ernest Zucker advocates the devaluation of the world's gold currencies by means of a one-third reduction in the gold content of the standard coins. He also advocates the introduction of silver as a subsidiary currency to facilitate trade with the silver-using East. The effect of the first proposal, he argues, would be to raise the prices of raw materials and similar commodities by about half, since their prices are world prices based on gold. The purchasing power of wages and salaries, on the other hand, would be reduced by about a third. In this way the disequilibrium between the prices of raw materials and manufactured products could be removed, while inter-allied debts and reparations would be reduced by a third. Dr. Zucker's scheme, however, presents serious difficulties. First there is the practical problem of securing common action among creditor nations, especially the United States and France. Secondly, devaluation would not in itself re-adjust the maldistribution of gold. Creditor countries would continue to attract the world's gold and if they persisted in high tariff policies, it would still be difficult for debtor countries to make payments, or for the volume of world trade to be increased.

Daily Mail Ideal Home Exhibition

THE *Daily Mail* Ideal Home Exhibition will be open at Olympia, London, W., on March 29–April 29 According to advance information recent developments in illumination will be utilised to create in the Grand Hall of Olympia, a 'Rainbow City'. The colours of a great rainbow, appearing from among 'clouds of depression', will be produced by a gigantic scheme of neon lighting, and the eye will travel back over a hall in rainbow hues to 'the sun of prosperity'. Scientific workers will be attracted by a series of "Rooms of the Scientists" on the first floor of the Empire Hall, where we are promised representations of the surroundings in which Newton, Faraday, Marconi and others carried on their investigations. A section of the Exhibition will be devoted to the home cinema, while close by will be the telephone exhibit of the General Post Office. Modern sanitation, heating and refrigeration apparatus, lighting schemes, general house equipment and labour-saving devices—indeed, everything for home service, comfort and recreation—are other and more usual features of the annual exhibition.

Land Utilisation Maps

THE Land Utilisation Survey has produced through the Ordnance Survey two one-inch sheets embodying some results of its work. These are sheets 114, covering the area to the south-west of London, and 142, showing the Isle of Wight, Portsmouth and the southern part of the New Forest. They are published at 4*s*. each and the sheet lines are the same as those of the popular 'one-inch' maps. Results are reduced from the original 'six-inch' survey and printed in six colours over the topographical detail and contours of the original ordnance sheets—on which the rivers appear in blue. Dark green shows forest and woodland, light green meadowland and permanent pasture, brown arable or tilled land, including grass grown in rotation and land lying fallow at the time of survey, yellow heathland, moorland, common and rough hill pasture and purple garden allotments and orchards. Land that is agriculturally unproductive, including built-over land, quarries, yards and roads is shown in red. Private parks and golf courses have been divided according to the use made of the land for grazing or other purposes. The maps are beautifully produced and give a striking picture of the uses to which land in Great Britain is put and should prove invaluable for many purposes. It is hoped to publish further sheets in course of time.

Dried Poultry Manure

THE possibility of making better use of poultry manure is receiving considerable attention at the present time and in the *Journal of the Ministry of Agriculture* (vol. 39, p. 656) R. Sayce and F. Hanley give an interesting account of the production of kiln-dried poultry manure. The kiln, which is very similar to that used in maltings, is a ventilated brick building with a corrugated asbestos roof which is lined with asbestos sheeting. It is heated with an ordinary coke furnace and a system of flues. After a preliminary drying in the air for about two days, the manure is spread on the kiln floor to a depth of 7–8 in., being turned occasionally during treatment. The time required for the drying process depends on the state of the material, its depth on the floor, weather and other conditions, but 48 hours should be sufficient for average material 6–7 in. deep, the maximum temperature during the process usually approaching 300° F. Four tons of manure may conveniently be treated at a time and will yield approximately two tons of dried material, which should not contain more than 7–10 per cent moisture if it is to store satisfactorily. Some loss of nitrogen during the drying is unavoidable, but analyses show that the final composition of the poultry manure closely resembles that of other organic fertilisers, which sell at £3 10s.–£5 a ton, at present in considerable demand in market gardening districts. In addition, the constituents are present in a readily available form.

Forest Products Research in the United States

THE valuable research work which has been carried out at the Forest Products Laboratory of the United States Forest Service, which is situated at Madison, Wis., is well known. According to Science Service, Washington, D.C., many difficulties are encountered in seasoning wood, and a treatment is being sought which will prevent, or greatly reduce, shrinking and swelling, thus removing one of wood's principal disadvantages. Fire-retardant treatment is under investigation and several combinations of chemicals are said to give promise of practical results. Great improvements in the manufacture, preparation and use of glues have been made in the last decade. Experiments which are being undertaken appear to show that plastic compounds from chipped wood or pulp fibres have possibilities of competing with other products for panels, tiles, mouldings and other articles, a development which the lover of the genuine article will not regard with great pleasure. Some other problems awaiting solution are forecast by Mr. Arthur Koehler, the officer in charge of sylvicultural relations at the Forest Products Laboratory. For example, joints and joint fastenings, now the weakest part of wooden structures, require improvement. It is held that wood could be made more attractive by colouring with transparent dyes or treatment with gases, such as ammonia, increasing lustre by transparent coatings, or treatment of wood itself. On the subject of wood working machinery scientific study is required as, for example, the development of a planer which would leave no marks, thus eliminating sanding and raised grain troubles.

Meteorological Records of Southport

FEW towns possess such accurate and long meteorological records as Southport. This is largely due to the late Mr. Joseph Baxendell, whose work has been carried on and extended by his son, for many years meteorologist to the Southport Corporation. Each year's records are summarised and discussed in an annual report; the report for the year 1931 has recently been published. There is a number of tables in these reports which differ in form from any of those appearing in the annual summaries of the Meteorological Office, and these add greatly to the value of the series. Among them may be mentioned those showing rainfall with different wind directions, diurnal variation of the duration of sunshine (totals for each hour of the day for each month) and mean level of subsoil water. This last table is a particularly interesting one. It has been maintained for forty-nine years, first of all by the late Mr. J. Baxendell at a private house in Liverpool Road, Birkdale, and later at 34 Kent Road, Birkdale, by Mr. James France and his wife. The record unfortunately ends at the close of the year under review, but alongside the last set of monthly figures appears similar information for the recently established meteorological station at Bedford Road Park, which is in the same part of Southport. To those not very familiar with this subject these single year's observations are not without interest, as they show differences of response to the meteorological conditions in spite of the proximity of the two wells used for making the measurements. June 1931 was very wet at Southport—5·99 inches of rain fell at Bedford Road Park—and the mean level of water in the shallower well at the older site rose in June almost to its February value, which was by no means the case at the other deeper well. The last six months of 1931 yielded altogether substantially more than the normal rainfall, but the average level of the shallower well almost returned to its normal value.

Electrification of the Swedish State Railways

THE primary object of electrifying the State railways in Sweden was to make them independent of foreign fuel. In 1920, when the project was first considered, the probable future price of locomotive coal was considered to be about £8 per ton. To make a more accurate estimate, local and English experts were consulted and they considered that the price would not fall below £2 15*s*. per ton. In spite of these estimates, the price of coal has continued to fall. In 1923 it was less than £2 per ton, it then fluctuated for several years about £1 per ton and it was only 16*s*. a ton in 1931. These fluctuations in the price of coal make it difficult to estimate the economy effected by electrification. At present, two sections of the Swedish State Railways are in electrical operation; the Ore railway in the north (280 route miles) and the Stockholm-Göteborg line (285 route miles). The electrification has increased the carrying capacity of the Ore railway by about fifty per cent and the average speed of the trains has been doubled. In a paper on the Swedish railways read to the Institution of Electrical Engineers on January 5, Mr. Öfverholm pointed out that the results on the Ore railway would have been more satisfactory if the existing station arrangements had been altered so as to allow longer trains to be employed. Considerable extensions of the system are being undertaken. By the end of the present year, 1,680 route miles of the State railways will be electrified. This corresponds to about forty per cent of the complete railway system. Several difficulties were experienced when electrification was first adopted. The disturbance on the telephone lines was obviated by suitably arranging the suspending wires of the power lines. By taking the power for the railway operation from the national distribution system, considerable economies were effected. The project of connecting the Swedish and Norwegian railways by a new bridge at Svinesund is being considered.

Andaman and Nicobar Islands

THE publication of the census report on the Andaman and Nicobar Islands (Census of India, 1931: vol. 2. Calcutta: Central Publication Branch; 7*s*. 6*d*.) has given an opportunity for the production of a valuable monograph on the aborigines of these islands, the cultural anthropology of the Nicobar natives and various reports on the forests, agriculture and trade. Most of these reports are by Mr. C. J. Bonington, but several other writers have collaborated in the work. The Andaman population of 19,000 shows an increase, but this increase is solely in the convict and other immigrant population. The aborigines have fallen in number to 460 compared with 786 ten years ago, 1,317 in 1911, and nearly 5,000 when contact with an introduced population began in 1858. There seems to be little hope of these races surviving. On the other hand, in the Nicobars, where there has been little disturbance with the natives or their tribal systems, the aboriginal population shows a steady increase during the last thirty years and is now nearly 10,000. The figures in several of the islands are based on estimates but there is no reason to doubt their accuracy.

Sterility in Domesticated Animals

A USEFUL bulletin has been issued from the Imperial Bureau of Animal Genetics, Edinburgh, (*2s. 6d.*), on the physiological and genetical aspects of sterility in domesticated animals. It is written by Dr. William Orr and Dr. F. Fraser Darling, and a full bibliography, prepared by Miss M. V. Cytovich, is appended. Successive sections deal with physiological aberrations in the reproductive system, the nutritional aspects of sterility, and types of sterility referable to genetical causes. This will be of service not only to all those engaged in practical animal breeding but also to those engaged in research on the physiological or genetical aspects of animal sterility.

Centenary of Sir John Kirk

IN connexion with the centenary on December 19 of Sir John Kirk (see NATURE, **130**, 920, Dec. 17, 1932), a portrait of Kirk was unveiled at the Zanzibar Museum, Zanzibar, by Sir Richard Rankine, British Resident for the Protectorate, in the presence of His Highness the Sultan. A number of exhibits associated with Sir John Kirk were displayed at the ceremony.

Effect of the Preying of Birds on Butterflies

MR. C. L. COLLENETTE writes from the Entomological Department, British Museum (Natural History), South Kensington, London, S.W.7, that he is making an investigation into the extent to which butterflies in the perfect or imaginal state are preyed upon in the British Isles by birds, and he would be glad to have any first-hand observations, giving, where possible, the species of both butterfly and bird, the date and locality, details of mode of capture, etc. Wings detached by the bird are of value, both as evidence of identity, and also by reason of the imprint of the bird's beak which is sometimes shown. Published records up to and including the year 1908 have been summarised in a paper by Sir Guy Marshall entitled, "Birds as a Factor in the Production of Mimetic Resemblances among Butterflies" (*Trans. Ent. Soc. Lond.*, 329–383, 1909). Mr. Collenette is making a search in both entomological and ornithological literature for British records published since this date, and he would be pleased to receive references especially in the lesser-known publications.

Announcements

A DISCUSSION on "The Raman Effect in Relation to Some Chemical Problems", to be opened by Dr. J. J. Fox, will be held at the Chemical Society on February 16, at 8 P.M.

DR. S. COURTAULD, a trustee of the National Gallery and founder of the Courtauld Institute of Art, Mr. E. G. V. Knox, editor of *Punch*, and Dr. N. V. Sidgwick, F.R.S., fellow of Lincoln College, Oxford, and member of the Advisory Council of Scientific and Industrial Research, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts or for public service.

THE next sectional meeting of the World Power Conference will be held at Stockholm on June 28–July 4. Reference was made to the programme in connexion with this meeting in NATURE of January 7, p. 22. Forms of application for membership can be obtained from the British National Committee, World Power Conference, 63, Lincoln's Inn Fields, London, W.C.2.

THE following have been elected officers of the Royal Meteorological Society for 1933:—*President:* Prof. S. Chapman; *Hon. Treasurer:* Mr. R. A. Watson Watt; *Hon. Secretaries:* Dr. J. Glasspoole; Mr. W. M. Witchell, and Dr. A. Crichton Mitchell; *Foreign Secretary:* Capt. C. J. P. Cave; *New Members of Council:* Mr. J. H. Field, Dr. B. A. Keen, Capt. W. N. McClean, and Dr. F. J. W. Whipple.

THE Central Scientific Company of Chicago has issued the first two numbers of a bulletin entitled *Cenco News Chats* which is meant to furnish to the public interested in instruments an up-to-date account of new developments in apparatus for which the Company is responsible. It is less formal than a catalogue, is well illustrated and does not enter into scientific details. We learn from it that the Bunsen burner with an H base with side entrance for gas and bottom for air is the most popular, and that the wire gauze over the flame should be iron 16 mils in diameter and 16 to the inch. Spectra photographed by means of a Wallace concave grating replica with a ruled surface only 28 mm. by 20 mm. are reproduced, and a short account of the Hahn X-ray spectrograph is given. Copies of the *News Chats* may be obtained on request from Messrs. Edwards, Allendale Road, London, S.E.5.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A temporary inspector in the Markets Division of the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S.W.1 (Feb. 20). A principal and head master of the Maidstone Technical Institute and Junior Technical School—Mr. A. W. Peacock, Education Department, Tonbridge Road, Maidstone (Feb. 25).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Origin of Curls and Twists in Wool Fibres

WILDMAN[1] has recently discussed the sequence of development of the fœtal lamb's coat, showing early anterior to posterior and later secondary progressions in follicle initiation over the skin surface. He directs attention to the spiral shape of wool follicles and the changes in direction of the growing point as development proceeds, concluding therefrom that the shape of the fibre is largely determined by the shape of the basal portion of the follicle.

The prototrichs characteristic of the natal coat, as described by Duerden[2], exhibit all shapes of tip from sickle to fine curly, the form being apparently related to the kind of growth which proceeds. Thus a gradual increase of thickness (presumably with progressive enlargement of the follicle growing zone) leads to the 'sickle tip' condition, while curly tip is associated with a mere elongation of extruded fibre without change of cross-sectional area. Irregular waviness is then exhibited in each prototrich before fibre production 'settles down' to that of the definitive fibre more typical of the adult coat and in general of more regular growth; that is, until the follicle population assumes its normal adult activity, when the definitive fibre structures continue as spirals, waves or with helical twists. The work of S. G. Barker and his collaborators[3,4] on 'crimp' apparently justifies the conclusion that a *straight* fleece fibre is extremely rare. The region of activity of the various forces imposing curl and twist upon the fibre must clearly lie within the lower parts of the follicle, although its characteristic shape may conceivably be modified by other forces, acting on the parts still surrounded by the follicle structure, such as varying rates and zones of dehydration (vide King and Nichols[4]). The direction of emergence of the fibre is generally not perpendicular to the skin surface and directional currents of fibre slope may be observed in many forms, though on the fleece areas they may be more or less obscured by the density of the fibre population, and, in the birth coat, by the tendency for groups of extruded fibres to approximate into the familiar lamb's coat 'spirals'.

The different forms of spirals (for example, horns in sheep) which result from larger accretionary growths have been discussed by Thompson[5] and Huxley[6] on mathematical premises based upon the existence of growth gradients about different axes of the growing region. A suggestion may be made that similar systems may operate within the comparatively restricted growth zones of hair follicles. It is conceivable that the forces within the follicle required to give rise to the various curved forms of fibre may follow upon different growth intensities (yielding different rates of elaboration of fibre substance) at different aspects of the follicle. Any asymmetry of the follicle growing zone could allow of differential rates of production of fibre constituents, while the disposition and orientation of the follicle in relation to the general growth gradients would affect the direction and magnitude of the forces at play.

Thus the form growth of the wool fibre would simulate in miniature that of the sheep's horn (omitting except in early stages the increase of cross-sectional area). The definitive fibre continues as a spiral, a uniplanar wave or with twist, whichever be the characteristic deformation associated with the type of follicle involved.

As a corollary to Thompson's studies of horn shapes and to the views here proposed, an explanation of the rarity of straight fibres in fleece growth seems possible. The essentials for a perfectly straight fibre would thus be symmetry of the basal portions of a follicle about a line perpendicular to the skin and the absence of differential intensity of growth. The follicle would have to be situated at a point of zero gradient, such as at the centre of a true hair whorl. These considerations would seem to render the production of a perfectly straight fibre extremely improbable.

Further Mutations in the Amphipod *Gammarus chevreuxi*, Sexton

NEW developments in *Gammarus chevreuxi* have appeared in the course of some experimental work on the question of the origin of recessive characters, and how far they may be present in the wild.

During the past twenty years we have examined more than half a million of these *Gammarus* as they were brought in from the wild, but with regard to the black retinular pigment of the eye, so far not a single variant has been seen. We have, however, found more particularly in recent years that variations occur in the amount of the white superficial pigment.

In the laboratory[1] on the other hand a number of recessive mendelian characters have arisen, principally relating to the eye, though in one instance[2], the 'white-body' of Stock II, the body colour was also affected. Changes of colour, such as red, white, purple, took place in the pigment of the retinular cells, and in one mutation, the 'albino' of Stock I, the cells themselves were lacking. In several stocks 'nowhites' appeared, that is, animals with none of the superficial white pigment in their eyes.

A new departure among the recessive characters that have recently appeared is a *red-eye* with which is associated *nowhite*, the two characteristics, namely, complete lack of both black retinular pigment and white superficial pigment not having up to now segregated from one another. The original black pair gave a black F_1 brood of 12, which, intermated, produced an F_2 of 49 blacks and 12 of these red-with-nowhites.

This new stock is a very distinct one, as proved by cross-matings with recessives of nine other strains, whitebody, lilac, six other and different reds, and the red-nowhite of Stock I. The last mentioned mating, red-with-nowhite with Stock I red-nowhite gave, for the first time in the nowhite matings of this species, normal blacks, that is, black eyes with the white reticulation.

Another new mutation is the *lilac-eye*. In this the recessive eye when hatched is a pale clear lilac colour, with white reticulation, but as the animal grows the white reticulation practically vanishes, and the colour fades from the centres of the ommatidia to collect in thin dark rings around the cone-margins, giving the effect of an eye composed of creamy white circles set in black or brown network. This, too, is a simple mendelian recessive. A curious occurrence must be noted in the blacks of the F_3 and F_4 generations of this lilac stock. Five of the females, normal in body colour and in the dark green gonad colour, gave white eggs; seventeen batches of eggs were laid, but no young hatched.

The other interesting new features of the experiment are the reappearance of the white-body mutation in the F_3 of another stock, and the reappearance of the Stock II red-eye (1922) in no less than five of the new stocks, three in the F_2 generation from the wild, and two in the F_3 and F_4.

Mated *inter se*, and with Stock II recessives, the results were as in Stock II, namely, red mated with red gave red; red ♀ mated with white II ♂ gave red; white II ♂ mated with red ♀ gave white young[3]. But with regard to the behaviour of the red pigment there is a great difference. In Stock II the distinction at birth is clearly marked between a bright red-eye normal body colour, and a white-eye white-body, but in at least three of the new stocks, there is considerable variation in the red-eye colour though the body colour is always normal.

Even in the same brood, the eyes at birth may be bright red, different shades of pink, or cream colour; the reds may lighten to pink or even cream, and the cream develop redness, or they may change but little. At the extreme limit of the change, the eyes are white and indistinguishable from the Stock II 'flushed whites', that is, eyes white with a very faint tinge of colour in two or three central ommatidia, yet they always function as reds. Similar variation in the concentration of the red pigment has already been found in the r_3r_3 types of Stock V, and among the reds known as Flesh[4].

Distribution of Molybdenum

I WOULD like to supplement Prof. H. ter Meulen's observations on the distribution of molybdenum in Nature[1] by repeating facts which so far have been published only in a preliminary report in a horticultural journal[2].

The character of an apple tree is profoundly influenced by the root system on which it is worked (budded or grafted); a particular variety may be rendered precocious or slow in fruiting, vigorous or dwarf in habit, resistant or susceptible to certain diseases, etc., by suitable choice of the rootstock on which it is worked. So far, it has not proved possible to imitate all these groups of effects by choice of soil and application of manure, but there is a general similarity between the effects of rootstock on one hand and of soil type and manuring on the other. Both soil type and manure are reflected in the elementary (especially the ash) analysis of the plant. It is known that different varieties of the same species of plant growing in the same soil differ in ash analysis, that is, each variety exercises a degree of selection in the proportions in which it takes up elements from the soil. If the rootstock continues to exercise this selective action after it has been worked, it can scarcely fail to exert an influence on the elementary composition of the scion. As a first attempt to apply chemistry to the elucidation of the mechanism of the effect of rootstock on scion, therefore, it was decided to examine the effect of rootstock on the elementary analysis of the scion, to seek for correlations between peculiarities in elementary analysis and horticultural character, and finally to attempt the modification of horticultural characters by modifying experimentally the elementary composition.

Accordingly, trees of the same variety but on two markedly different rootstocks grown close together were in the summer of 1928 separated into various anatomical fractions and 'ashed'. The ashes were examined spectroscopically by Prof. H. Dingle of the Imperial College, London, who reported many quantitative differences between the ashes of corresponding parts of the trees on the two rootstocks and one qualitative one; the six trees on rootstock type ix contained molybdenum, the element not being detected in any of the ten trees on rootstock type xii. In the young trees so far examined, the molybdenum was restricted to the woody parts of the roots and of the stem up to about the level of the graft union, none being found in tissues external to the wood or in any part above the union.

Preliminary experiments in which potassium molybdate was injected into the tops of young trees on rootstock type xii failed to demonstrate any significant effect, but material of varying ages is now ready for injection of molybdates into all parts, including the roots, in the hope of throwing light on the function of the element.

The effect of molybdates on the polarisation of organic acids[3] invites speculation as to the function of molybdenum.

Fluorescence of *Lolium* Seedlings in Ultra-Violet Light

DURING the past three seasons (1930–32) we have carried out selfing, hybridisation and back-cross experiments with *Lolium perenne* L. and *Lolium multiflorum* Lam. with a view of ascertaining the mode of inheritance of the factors responsible for the ultra-violet light fluorescence reaction. The considerable amount of data now to hand strongly confirms our original expectations[1].

(1) The capacity to fluoresce is heritable.

(2) Normally *L. perenne* is pure for non-fluorescence and *L. multiflorum* for fluorescence.

(3) Fluorescence is dominant in the F_1 generation of the cross, pure fluorescent × pure non-fluorescent.

(4) The F_2 generation gives a ratio not significantly differing from 3 fluorescent to 1 non-fluorescent.

(5) The back-cross F_1 × pure fluorescent gives all fluorescent progeny and the back-cross F_1 × pure non-fluorescent gives a ratio approximating to 1 fluorescent to 1 non-fluorescent.

(6) We have found no genetic linkage between fluorescence and (*a*) the possession of awns on the lower flowering glumes, (*b*) shoot vernation, (*c*) longevity (data limited), or (*d*) vigour (data limited).

A number of these conclusions do not agree with those of Nilsson[2], but some of them are in agreement with deductions derived from 1931 selfing experiments reported by Corkill[3]. In our work the F_1 plants from the crosses *L. perenne* × *L. multiflorum* and vice versa were highly self-sterile; this made genetic analysis more difficult.

The investigation was designed to elucidate the curious fluorescence behaviour of *L. perenne* strains. Broadly speaking, each strain has a constant content of fluorescence reactors (after making due allowance for the admixture of *L. multiflorum* which is present to some extent in most commercial lots). This content is lowest in the case of superior (from an agronomic point of view) and highest in the case of inferior strains. We have examined some sixteen different strains from nine countries and find the correlation distinct and striking. It is particularly noticeable in the case of New Zealand lots [1, 4].

The content of fluorescent reactors thus provides a gauge of agronomic merit. This might be ascribed, at first sight, to the non-fluorescent fraction being *ipso facto* superior to the fluorescent portion in each strain, the latter representing the segregants of *L. perenne* × *L. multiflorum* crosses and the fluorescence being linked to the *L. multiflorum* 'inferior' characters. This theory is, however, untenable, since we have not, so far, found any evidence of linkage between fluorescence and (*a*) biennial habit, or (*b*) growth vigour. Further data are required in this connexion.

An alternative tentative hypothesis, which seems more likely, depends on the assumption that *major* degeneration in *L. perenne* strains is due to hybridisation with *L. multiflorum* in the first instance. There is collateral evidence for this view. These so-called species readily inter-cross, and although the F_1 plants are partially self-sterile, back-crossing takes place without difficulty. Segregants of such crosses are inferior from an agronomic point of view. The proportion of *L. perenne* × *L. multiflorum* heterozygotes present in a strain (and hence the degree of agronomic degeneration) is the resultant of a complex of causes mainly of a cumulative and interdependent nature, and its rate of increase or decrease depends on the balance between the group of influences tending to cause and perpetuate hybrids and the group operating in the other direction. Should equilibrium between these groups be attained (and assuming random mating) the proportions of homozygotes and heterozygotes present in the population would remain constant from generation to generation. This is true in respect of the characters directly governing agronomic value; it is also true of those concerned with fluorescence capacity. On the other hand, should equilibrium be disturbed so as to favour the production and perpetuation of hybrids, then the strain as a whole would deteriorate. But such a deterioration would necessarily be accompanied by an increase in fluorescence reactors. Consequently, the content of fluorescence reactors must be proportional to the degree of hybridisation, and hence of agronomic degeneration. It follows that the fluorescence content of a strain of *L. perenne* is a measure of its agronomic merit, not because the reacting individuals are inferior to the non-reacting ones by reason of linkage with inferior agronomic characters, but because it gauges the amount of *L. multiflorum* 'blood' in the strain as a whole.

In contrast to what we describe above as *major* degeneration, there will naturally be deterioration in cases where unfavourable selective influences act on populations of pure *L. perenne* individuals in the absence of *L. multiflorum* or hybrids. We have no reason to think that such relatively *minor* degeneration can be measured by a fluorescence test.

Teaching of Biology

I SHOULD like to comment on the account of the proceedings of the Association of British Zoologists, so far as they relate to zoology in secondary schools[1]. I write as a schoolmaster, knowing that my views are to some extent shared by others.

(1) We do not need vacation courses of the type of many now provided. Whereas the university lecturer is usually a specialist, the sixth-form master must have a good knowledge in all branches. Here are the subjects of four questions which have recently been set for schoolboys: the amphibian organiser; the structure, development and function of nephridia; adaptive radiation of insects; ciliary action. I do not complain of these, but I do ask that the universities which set such questions recognise that there are men in the schools who can answer them, and are thirsting for more knowledge of the same standard. I believe the Board of Education uses the term 'refresher course', and refreshes our memories of the dogfish and frog. What we need is instruction in recent advances, and contact with those engaged in research. Much might be done here informally, at least for schools near universities, and formally by the granting of a sabbatical year, in which the schoolmaster could attend a university course. Obviously the latter cannot be realised without the approval of the Board of Education.

(2) I welcome Prof. H. G. Cannon's suggestion that improvement must come through university syllabuses; for pupils who are dependent on scholarships for their college career or on the School Certificate for their livelihood, it is the only way in which it can come.

(3) Few biology teachers have trained laboratory assistants, yet most of us are sent out from the university with no notion of how to do such things as culturing *Amœba* or killing a rabbit, unless we learnt at school. It should not be impossible to

include more 'laboratory method' in a university zoology course, with advantage to others besides the future schoolmasters. Fieldwork—both collecting and ecology—might also have more attention paid to it. Most of what I have written applies, *mutatis mutandis*, to botany also.

Nuclear Moments of the Gallium Isotopes 69 and 71

An examination of hyperfine structure in the visible lines of the Ga II spectrum with a Fabry-Perot interferometer has shown the patterns due the individual isotopes to be distinctly separated by a difference in the magnetic moments of the nuclei. This permits the mechanical moments to be separately determined as $i = 3/2$ for both isotopes, in accord with previous determinations from incompletely resolved structures in Ga I lines[1] and Ga II lines[2]. The ratio of the $g(i)$ factors, given by the relative magnitudes of the hyperfine term separations, is 1·27, the less abundant isotope 71 having the larger magnetic moment.

These results are obtained from the structures of the $4s5s\ {}^3S - 4s5p\ {}^3P$ and $4s5p\ {}^3P - 4s5d\ {}^3D$ lines. The $4s4d\ {}^3D - 4s4f\ {}^3F$ lines, although not as well resolved, stand in qualitative agreement. The observed structure of the line ${}^3S_1 - {}^3P_0$ λ 6456 is given in Fig. 1, together with the term schemes. The centre of gravity of the 69 triplet, calculated from the theoretical intensities, falls at 0·389 cm.$^{-1}$, that of the 71 triplet at 0·393. Since the difference between these is not much greater than the probable errors in the measurements, it is safe to conclude only that an isotope shift, if present, is very small. The fact that components a' and b, of theoretical intensities 3 c_{71} and 2 c_{69} respectively, are photographed with very nearly equal densities at various exposures, gives the abundance ratio $c_{69}/c_{71} = 1{\cdot}5/1$.

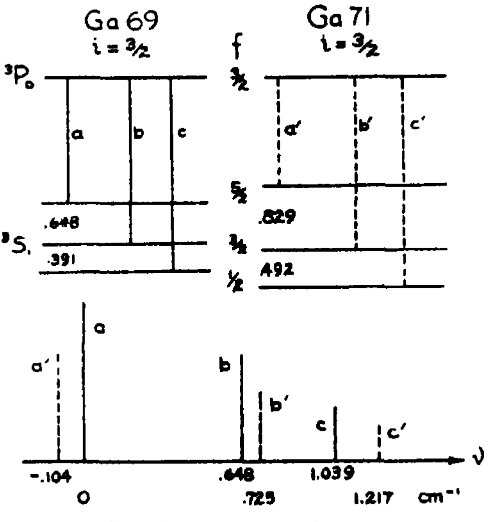

Fig. 1.—Hyperfine structure of λ 6456 in the spectrum of singly ionised gallium. The components due to 69 are indicated with full lines, those due to 71 with dotted lines.

The difference between the $g(i)$ factors observed here is noteworthy in that the only other example of isotopes with equal spins and unequal hyperfine separations is that of thallium, where the lighter isotope (as in the present case) exhibits separations 1 or 2 per cent smaller than those of the heavier isotope[3]. The remaining isotope pairs which have been reported with some certainty to have equal spins are copper 63, 65[4]; bromine 79, 81[5]; cadmium 111, 113[6]; rhenium 185, 187[7]. None of these has shown a perceptible difference in the hyperfine separation constants. It is true, however, that the hyperfine structure of the last four elements named is not so well suited to the observation of small differences as is the structure of the thallium lines, and it is possible that the gallium isotopes are exceptional only in the degree to which their magnetic moments differ.

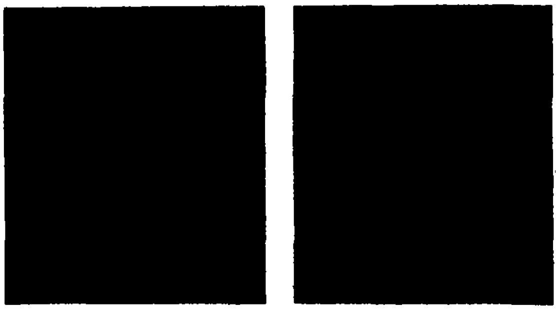
Negative Polarisation in Fluorescence

In an important paper[1] Wawilow has reported measurements on the polarisation of fluorescence of solutions of some dye-stuffs in glycerine, when excited by radiations of different wave-lengths. Using for excitation the radiations from a mercury lamp, isolated by a quartz monochromator, he finds that the degree of polarisation shows a marked dependence on the wave-length of the exciting light. Starting from the visible region of the spectrum, as the wave-length of the exciting light is diminished the degree of polarisation decreases rapidly, passes through a minimum value (corresponding, in general, to excitation by λ 3125–3131), and rises again as we proceed farther towards the ultra-violet. The minimum value is usually *negative*; that is, the intensity of the fluorescent vibrations along the direction of propagation of the incident light is greater than that of vibrations in the perpendicular direction.



(*a*) (*b*)

Fig. 1.

It is known, however, that the light that issues from a quartz (crystalline) monochromator is, in general, considerably polarised, and that the direction and the extent of polarisation fluctuate as we proceed along the spectrum. We have therefore repeated

Wawilow's measurements using linearly polarised light for excitation and observing along the normal to the plane containing the direction of propagation and the direction of vibration of the exciting light. Though our values differ considerably from those calculated from Wawilow's results (the polarisation varies also with the concentration of the dye-stuff), the general nature of the variation of polarisation with the exciting wave-length, and also its negative value for excitation by λ 3125–31, are fully confirmed. The change in sign of the polarisation in the case of fluorescein solution occurring when the exciting wave-length is changed from λ 4358 to λ 3125–31, is seen clearly in Fig. 1 (*a*) and (*b*), which are photographs of the fluorescent radiations excited by λ 4358 and λ 3125–31 respectively, taken through a suitably oriented Savart plate and analyser. The images of a fixed cross-wire which appear in the photographs, serve as reference for the positions of the fringes. It is easily seen that whereas in Fig. 1 (*a*) the centre of the cross-wire falls on a bright fringe, it falls on a dark fringe in Fig. 1 (*b*).

Also observations along different directions show for λ 3125–31 excitation that the intensity of the fluorescent radiations vibrating normal to the direction of the vibrations of the exciting light is always greater than that of fluorescent vibrations along the direction of the exciting vibrations.

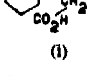
Synthesis of Chrysene and Certain Derivatives

THE very interesting letter of Messrs. Cook, Dodds and Hewett[1] on the subject of the œstrus-producing action of a keto-tetrahydrophenanthrene contains a statement that experiments are being made with the object of converting this ketone into ketohydroxyœstrin.

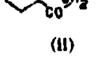
We have also been engaged in synthetic studies in this group for some time and therefore, in the hope of avoiding duplication of research, we take an early opportunity of indicating the lines on which we are proceeding.

The method is similar in principle to that of Braun and Irmisch[2] but the stages are effected in a different manner and the yields of pure products have been greatly improved.

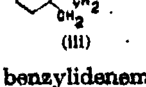
β:β′-Diphenyladipic acid (i) (*meso-* and *rac-*), is accessible in several ways, for example, by reduction of ethyl cinnamate (or benzylidenemalonic ester, etc.) by means of aluminium; it suffers twofold dehydration on treatment with hot 85 per cent sulphuric acid giving the diketohexahydrochrysenes (ii) (*cis-* and *trans-*). Reduction of the *cis*-diketone by Clemmensen's method affords a hexahydrochrysene (iii) the constitution of which is confirmed by its dehydrogenation by selenium to chrysene (iv).



(i)



(ii)



(iii)

(iv)

Starting with the appropriate substituents in the benzene rings (possibly β:β′-dianisyladipic acid will serve the purpose) we can see our way, as clearly as any paper-synthesis allows, to the preparation of a *nor*ketohydroxyœstrin, *that is*, the natural product without its angle-methyl group.

Sex Hormones and Cancer-Producing Compounds

A SEQUEL to the formulation of the sterols and bile acids as hydrogenated phenanthrene derivatives[1] was the suggestion[2] that carcinogenic derivatives of 1 : 2–benzanthracene might arise by abnormal sterol metabolism. No experimental evidence for ring-closure to the hydrogenated benzanthracene ring-system has yet been put forward. Whether this actually occurs or not, it seems probable that the formation of a carcinogenic compound from a sterol would involve dehydrogenation to the aromatic state, for reduction of 1 : 2 : 5 : 6–dibenzanthracene to an octahydro compound results in loss of carcinogenic activity. Recent investigations of the ovarian hormones support the view that such sterol dehydrogenations do occur in the animal body. Thus œstrin is a tetracyclic compound which contains one aromatic ring, and Girard[3] has recently isolated from the urine of pregnant mares an œstrogenic compound which undoubtedly contains two aromatic rings.

For reasons such as these, and because the cell proliferation which characterises the œstrous state is in some respects reminiscent of the early stages of a malignant growth, we have sought a correlation between substances having œstrogenic action and those having carcinogenic properties. Four main lines of attack have been initiated. These are:—(*a*) The production of synthetic compounds of known constitution which possess œstrogenic properties. One such substance, 1–keto–1 : 2 : 3 : 4–tetrahydrophenanthrene, has already been described[4]. (*b*) The examination for œstrogenic activity of compounds containing the same ring-system as carcinogenic hydrocarbons, but with polar groups present and with some rings partially reduced. One such compound, 9 : 10–dihydroxy–9 : 10–di–*n*–butyl–9 : 10–dihydro–1 : 2 : 5 : 6–dibenzanthracene[5] has now given positive results. (*c*) In addition, we have found œstrus-exciting activity to be possessed by the two most potent carcinogenic hydrocarbons yet known, namely, 5 : 6–*cyclo*penteno–1 : 2–benzanthracene[6] and 1 : 2–benzpyrene[7]. We confess that this last result was entirely unexpected; it is very striking that both types of biological activity should be shown by one and the same compound. (*d*) The examination for carcinogenic activity of œstrin and related compounds, especially the basic aromatic hydrocarbon 1 : 2–*cyclo*pentenophenanthrene, is being undertaken.

The technique of testing for œstrous activity was that described in NATURE of January 14. The difficulties of solubility of the three compounds reported was very much greater than was experienced hitherto, and in *all three cases 100 mgm.* of substance was injected in a suspension in sesame oil. It is impossible to obtain any idea of the potency of the substances relative to œstrin from these determinations owing to the extremely slow absorption. These tests must therefore be regarded as qualitative reactions for œstrogenic activity, but the results are none the less conclusive. The 9 : 10-dihydroxy-9 : 10-di-*n*-butyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene, when injected in the quantity described above, gave a full œstrous response in all the ten animals injected, and the œstrus is continuing after 150 hours. With regard to the two carcinogenic hydrocarbons, 5 : 6-*cyclo*penteno-1 : 2-benzanthracene gave four œstrous responses lasting 150 hours out of ten animals, whilst 1 : 2-benzpyrene gave three œstrous responses lasting 150 hours out of ten animals. It would appear from these results that these two latter compounds have a feebler œstrus-producing action than the former.

In reporting these very suggestive results, we wish expressly to emphasise that, at the present stage, there is no evidence whatever that carcinogenic compounds arise from œstrin in the animal body. We merely record our observations that pure synthetic compounds of known molecular structure can possess both carcinogenic and œstrogenic activity.

We have commenced experiments (in collaboration with Mr. C. L. Hewett and Mr. W. Lawson) which have as their aim the synthesis of ketohydroxyœstrin and compounds of allied structure.

Glutathione, Iodoacetic Acid and Glucose Metabolism

WITH reference to Dr. Dickens's interesting letter in NATURE of January 21 (p. 130) I may, perhaps, be allowed to make a brief statement. My colleague, Mr. A. H. M. Wheatley, and I submitted for publication in the *Biochemical Journal* on November 1 a paper containing the following observations.

(1) The toxicity of iodoacetic acid *in vivo* is greatly diminished or eliminated by admixture with sodium thiosulphate. Iodimetric estimations showed that one molecule of iodoacetic acid combines with one molecule of sodium thiosulphate.

(2) The powerful inhibitory action of small concentrations of iodoacetic acid on the oxidation of glucose by brain tissue is diminished or eliminated by the addition to the brain tissue of glutathione, cysteine or sodium thiosulphate. The evidence showed that there is a direct interaction between the sulphur compounds and iodoacetic acid, the halogen atom of this acid being clearly very labile. Dr. Dickens's observations support this conclusion.

(3) It appeared possible from the evidence that the toxicity of iodoacetic acid towards biological processes might be linked with its ability to combine easily with sulphydryl compounds, and, hence, that the naturally occurring sulphydryl compound, glutathione, might be playing some part in the processes inhibited by the halogen acid. This conclusion was confirmed by experiments on the action of glutathione on the fermentation of glucose by baker's yeast under aerobic conditions. It was shown that the addition of glutathione to baker's yeast increases the rate of carbon dioxide output in presence of glucose to a value approaching that obtained by the yeast under anaerobic conditions. The oxygen uptake, on the other hand, was slightly inhibited by the presence of the sulphydryl compound. Glutathione affects markedly the relationship between fermentation and the respiration of yeast in the presence of glucose.

The observations recorded above were made before the appearance of Lohmann's paper on the influence of glutathione on glyoxalase activity. It is likely that there is a close connexion between the effects of glutathione on glucose breakdown on one hand and glyoxalase activity on the other, and the conclusion seems warranted that glutathione in the living cell plays a dominant rôle in the dynamics of glucose metabolism.

Rate of Burning of Colloidal Propellants

IN NATURE of January 14, A. D. Crow and W. E. Grimshaw have discussed our method of analysing some of their experimental results, and offer the following criticisms :

(1) The method of correcting for energy losses is invalid when applied to differential methods of analysis.

(2) A simplifying approximation we make in calculating the correction leads to serious error.

The first criticism is beside the point, since our method is not a differential method. After adequate trial we discarded both differential and integrating methods and our reasons for doing so are stated in our paper. Our method is a direct method, each point on our curves being based on one observation and one only of pressure and time, independent of previous and subsequent observations. The cooling correction applied at each point is based on the same assumption as that of Crow and Grimshaw, namely, a mean gas temperature holding up to the moment under observation. This assumption is sufficient for the purpose of assessing the energy loss up to this moment, provided the mean temperature does not differ greatly from that at complete combustion. Except for the first two or three observations of each series (which we discard) this condition holds. The resulting corrections to the observations retained are never large enough to mask the effect under investigation.

The simplifying approximation referred to in the second criticism leads to errors of less than one per cent for all observations retained ; the resulting displacement of the points on our curves is imperceptible.

The promise of additional material including temperature observations relieves us of the necessity of pursuing this subject further in its present form.

Mother Goddess in India. Mr. Kalipada Mitra discusses in the *Indian Antiquary* for December the affinities of the Gây Ḍâṇṛ festival in its bearing on the cult of the mother goddess in India. It is suggested that it is a survival of a ceremonial sacrifice offered in the past to the corn goddess, especially because of its close association with the terrible goddess Kâlî, her Lakṣmî and Alakṣmî and the Feast of Lamps. A festival known as the *Gârśî Vrata* is observed in several districts of Bengal by women only in the very early hours of the morning on the last day but one of the year for the benefit of the cattle and the household. This is a peculiar form of worship of Lakṣmî. In several districts a clay figure of Alakṣmî is mutilated by cutting off the ears and nose, after which Lakṣmî is ceremonially installed in the house. The offerings made consist of plantains, coconut, etc., but must not include any produce of the ploughshare. In Vikrampur, when the household rises, a conch is blown and a torch is lit and carried into every room while an elderly woman chants verses ordering out vermin and bidding Lakṣmî enter. In eastern Maimansingh this ceremonial is regarded as some sort of worship of a deceased mother-in-law. An effigy of the mother-in-law in the form of a rice-paste female figure with a babe in her lap, accompanied by rice-paste figures of four kites and four crows with the effigy of a pig, is set up by a small tank dug in the courtyard for the purpose. When the pig has been sacrificed to the female figure, she with the other figures are buried in the tank. This ceremonial seems to lead up to the ancient cult of the mother goddess. Similar figures in terracotta have been found at Patna, Buxar and Kumrahar, through which both in form and association connexion is here traced with the figurines of Mohenjo-daro and Harappa as well as with the mother-goddesses of Sumer and Crete.

Late Neolithic Fortress, Homolka, Bohemia. A preliminary report on the excavation of a late neolithic fortress at Homolka in Bohemia by the second and third archæological expeditions to Central Europe of the Peabody Museum, Harvard University, and the University Museum of Philadelphia, in the seasons 1930, 1931, is made by Vladimir J. Fewkes (*Proc. Amer. Phil. Soc.*, 71, No. 6). A preliminary reconnaissance in 1929 tested nineteen sites in Bohemia which yielded evidence of fourteen different cultural phases from the earliest neolithic to twelfth century Slav. The top of Homolka resembles a roughly pointed horseshoe, greatest length a little less than 100m. and greatest breadth 60m. It belongs to the so-called 'Nordic' phase of neolithic culture, approximately 2,000–1,800 B.C., and represents the closing stage of the neolithic in this part of Europe. One hundred and forty-seven culture pits, representing for the most part dwelling-foundations, were excavated. Nineteen definite huts, indicated by well-defined traces of posts, were found. Pits and post-holes were cut in shale. Huts ran in rectangular shapes, approximately 4·25–6·50 m. in length and 3–5 m. in width. Three rows of posts, two walls and a centre line supporting the ridge pole are characteristic of the earlier huts. Sub-pits, three or four in number, are usual, their purpose being distinguishable, such as fire-pits, work-shop with anvil, etc. Fireplaces of clay, or in one case with a pebble-bed, and, possibly, traces of benches were observed. The walls were plastered on light parallel poles. There is no evidence of wicker-work of wattle and daub. Two palisades, belonging to different periods, were present. Pottery was found in large quantities, and is now being studied with important results. The oldest type shows affinities with Jordansmühl. Later, innovations were introduced from both south and north. Quantities of bone and antler work and shells from the Mediterranean or Adriatic were found. The site is a unique archæological monument in Central Europe.

Effect of Pit-Head Baths. The *Human Factor*, vol. 6, No. 12, contains an article on "Pit-Head Baths", by Mr. J. H. Mitchell, who is the holder of a Miner's Welfare national scholarship, and qualified to speak from personal experience. He sketches the origin and development of the scheme, and the reasons and prejudices behind the miners' initial rejection of it. These, he alleges, are, their fundamental conservatism, natural opposition to the necessary weekly deduction from wages, and a host of curious yet real objections, such as distrust of the employers' real intentions, and fear of too much washing. He gives a clear exposition of the installation of the baths, and the procedure adopted, and details the far-reaching effects, both observed and to be expected. Six months after their inception, lost time due to sickness and accidents was definitely decreased, although voluntary absenteeism (for reasons he explains) had arisen. Demands for overtime are frequent and unforeseen in the industry, and the invigorating effect of the bath facilities have proved physically and psychologically invaluable. Mr. Mitchell foresees, as a consequence, a great change in the miner's home life.

Birds of the Natuna Islands. The Natuna Islands extend for some two hundred miles in the South China Sea, north-west of Borneo. They comprise a few main islands, with numerous islets and rocks. Ornithological knowledge of the Islands dates from 1893, and now Harry C. Oberholser reviews all the information bearing upon the birds of this interesting area (Smithsonian Institution, *U.S. Nat. Mus.*, *Bull.* 159, 1932). The fauna is of the continental island type, its relationships being with the other islands of the South China Sea and the neighbouring land masses. Of 108 breeding species and sub-species (19 species occur as migrants only) 26 are peculiar to the Islands, their nearest relatives being in Borneo (12), the Malay Peninsula (11), Sumatra (9), the Anamba Islands (4), and Java (2). Of the 76 remaining forms, some are confined to a limited East Indian area, while others have a wide range in the Oriental and Australasian regions. Analysis shows that the birds of the Natuna Islands are most closely related to the fauna of Borneo, less closely and about equally to the faunas of the Malay Peninsula and Sumatra, about half as much to Java as to Sumatra, still less to the Anamba Islands, and least of all to Indo-China.

Nerve-Net of Hydra. Carl H. McConnell (*Quart. J. Micr. Sci.*, 75, Pt. 3, 1932) has traced the development of the ectodermal nerve-net in the buds of *Hydra*. After trial of various methods of vital staining, he adopted the rongalit white technique, which is carefully described. The nerve cells develop from the interstitial cells of the ectoderm and by the time the tentacle area makes its appearance in the bud, the interstitial cells which are to become nerve cells begin to send out processes between the epithelio-muscular cells of the newly forming ectoderm, and as further development proceeds a small area of nerve-net is formed by the growing together of processes from the ganglion and sensory cells. These processes advance in a pseudopod-like manner between the epithelio-muscular cells until they meet and fuse with processes from other ganglion cells. Other processes from the ganglion cells grow out in various directions and end among the muscle processes of the epithelio-muscular cells but there are no differentiated nerve endings. It appears that the long connecting processes develop first and the short, free-ending motor processes later. The author states that on many occasions he has been able to observe a perfect net under the epithelium of brown *Hydra* but the connexions between the nerve elements are easily broken by pressure of the cover-glass. The development of the nerve-net proceeds downwards from the tentacular to the basal or foot pole of the *Hydra*. The author found no connexions between the nerve cells and the cnidoblasts. He figures developing sensory cells and developing and fully formed ganglion cells, bipolar and multipolar.

Eradication of the Stinging Nettle. The distribution and control of the great stinging nettle, *Urtica dioica*, is the subject of an interesting article by G. H. Bates in the *Journal of the Ministry of Agriculture*, vol. 39, p. 912. Although not an arable weed, this plant frequently becomes troublesome on grass, and apart from any other reason it gives a general appearance of neglect on property where it occurs in any great quantity. A careful study of the chief natural habitats of the nettle have led the writer to refute the old idea that it is a nitrophilous and shade-loving plant and actual soil analyses are brought forward in support of his view. Cover, rather than high nitrogen content, was found to be characteristic of the sites most liable to infestation, and the chief causes of an invasion of nettles on grassland, molehills, stick heaps, ditch clearings for example, bear out this theory. As regards the best methods of eradication of nettles from grassland, opinion is somewhat various, but both chemical and mechanical means have been used successfully. As an example of the first type of method, spraying with a 5 per cent solution of sodium chlorate may be mentioned. This has proved very successful on the Continent and should be applied at the rate of 1 gallon per square yard after the shoots have been cut down so as to ensure the underground parts of the plant being reached. A simple but effective mechanical method of eradication is cattle treading. The placing of a feeding trough or salt lick in the middle of a patch of nettles has been shown to bring about a complete clearance of the pest, and the consolidation of the ground only temporarily affects the grassland itself.

Pitchblende at Great Bear Lake, Canada. It is already well known that the pitchblende deposits at LaBine Point, though difficult of access, probably constitute the most valuable source of radium yet discovered. A comprehensive report on the occurrences has been prepared by H. S. Spence (Investigations of Mineral Resources and the Mining Industry, 1931, pp. 55–92, 1932, Department of Mines, Canada). Four types of mineralisation have so far been found: (*a*) pitchblende-quartz veins with important amounts of native silver; (*b*) native-silver-rhodochrosite veins; (*c*) silver-cobalt-carbonate veins; and (*d*) cobalt-bismuth-quartz veins. Of these, (*d*) is definitely later than the others, the relative ages of which have not yet been established. Samples of pitchblende taken at a dozen different openings on the two principal veins, representing roughly hand-graded ore, have been analysed in detail. They show 25·73–52·68 per cent of uranium and 5·82–13·40 per cent of lead. Atomic weight evidence has proved that the lead is almost pure uranium lead, corresponding to the facts that thorium is absent from the mineral and galena no more than a very rare accessory. The age of the pitchblende is estimated at about 1,300 million years, a figure which presumably implies an early Pre-Cambrian (Keewatin) period of ore deposition. It is of interest that the samples giving the lower values for uranium are leached surface specimens. The presence of rich deposits of native silver adds additional interest and economic value to the occurrences.

Rainfall in Dahomey. "Die Niederschlagsverhältnisse des alten deutschen Schutzgebietes Togo" is the title of a memoir by Dr. Raoul Pignol which is No. 6 of Band 49 of *Archiv der Deutschen Seewarte*, but is published separately. It deals with the climate—more particularly the rainfall—of what used to be the German colony of Togoland. The greater part of this area is now incorporated in Dahomey. On a basis of rainfall and temperature, following the system of classification of climate devised by Köppen, the country must be divided into three principal zones, which show characteristic vegetation. The southern coastal belt has two rainy seasons separated by a short, dry season in summer and a relatively long one in winter, and is classified as isothermal (annual range of temperature less than 5° C.); from the northern boundary of this zone up to about latitude 8°, the isothermal character is maintained, but in general there is only one wet and one dry season, the dry season extending from November to February or March; farther north the annual range of temperature exceeds 5° C. and the dry season is longer, extending from October or November to April or May. The rainy and dry seasons occur, according as the monsoonal indraught from the Gulf of Guinea or the dry harmattan—a north-east wind drawn from the Sahara—prevails. The analysis of the available rainfall data has been carried out with Germanic thoroughness. The different types of seasonal variation of rainfall are illustrated by graphs for representative stations, and these are followed by the main objective of the work—rainfall maps on a good open scale, showing the geographical distribution of annual, seasonal and monthly rainfall. Apart from their economic value, these are instructive examples of the monsoonal control of climate, and may usefully be compared with similar data for India.

Aeroplane Noises. The issue of the *Proceedings of the Physico-Mathematical Society of Japan* for October 1932 contains the second of two papers on the sounds emitted by revolving air screws which Messrs. Obata, Morita and Yosida have recently contributed to the Report of the Aeronautical Research Institute of Japan. Models, of about a third natural size, of six air screws were used. The driving shaft projected through the outer wall of a building from a boxed-in electric motor and the sounds were recorded by microphone, amplifier and oscillograph. They are of three types—those due to the rotation of the screw, those due to the shedding of eddies from the blades and those due to the elastic vibrations of the shaft and blades. The oscillograph records are not strictly periodic but a representative period is analysed and the amplitudes of the component harmonics at different speeds of the screw and in different directions from it, are shown by means of curves. Full-scale observations on a moored aeroplane provided with a silencing pit were made for the Aircraft Noise Sub-Committee of the Aeronautical Research Committee in Great Britain by Mr. C. F. B. Kemp and were described by him in the March 1932 issue of the *Proceedings of the Physical Society*, London. His results are in partial accord with the theory of Dr. Paris while those of Obata, Morita and Yosida are not.

Polarisation Phenomena in Electron Scattering. E. Rupp has described further experiments on the polarisation effects obtained by scattering electrons at gold surfaces (*Phys. Z.*, Dec. 1). In his earlier experiments, the electrons scattered at 90° by a gold foil were passed through a second thin gold foil and an intensity variation was found around the ring pattern. The latest experiment was conducted by scattering the electrons by a gold foil and allowing a pencil of electrons scattered by a gold foil to fall alternatively on a gold or an aluminium wire which acted as a second scatterer. The electrons leaving the wire in two directions parallel and antiparallel to the original electron beam were separately collected. The apparatus was adjusted until the ratios of parallel to antiparallel scattering were equal for the gold and aluminium wires, using 20 kv. electrons which were assumed not to show polarisation. When 130 or 250 kv. electrons were used this equality was not maintained, a polarisation effect altering the ratio by 3–4 per cent and 9–10 per cent respectively. The polarisation effect was destroyed by passing the electrons through a transverse magnetic field 10 cm. long and of intensity 440 gauss. (The direct deflection was compensated electrostatically.) The unsymmetrical reflection is ascribed to a magnetic moment of the electron, and its polarisation to scattering at the atomic nuclei.

Astronomical Topics

Large Group of Sunspots. A large group of sunspots in stream formation is at the present time crossing the sun's disc. The spots appeared at the eastern edge of the disc on February 1 and will disappear around the western edge on February 14; the date of central meridian passage was February 7·5. On February 2–3, the total area of the stream was 1500 millionths of the sun's hemisphere, and the area of the largest component (the following spot) about 700 millionths. This group is the largest for two years, and its appearance at the present time is an example of the vagaries of sunspots. During the last three years, the sun's activity has been declining fairly rapidly towards the minimum of the 11-year cycle, and last year on about ninety days the sun was entirely free from spots; yet the present sunspot disturbance is the third considerable group seen in the last three months. An interesting feature of this group is the inclination (about 20°) of its axis to the sun's equator, the leader spot, in latitude 16° N., being farther away from the equator than the follower in latitude 11½° N. On February 2, the spots were active spectroscopically, and two small eruptions of bright hydrogen ($H\alpha$) were observed at Greenwich at 10^h and 15^h.

Perturbations of Comets by the Stars. A paper by E. Opik (*Proc. Amer. Acad. Arts Sci.*, Oct.) examines the effect of stellar perturbations in the case of comets or meteors which travel to great distances from the sun. It is easy to see that, since it is only the difference of action on the comet and on the sun that is effective, it is necessary to proceed to great distances before these perturbations are of any importance. It is shown that one of the effects of such perturbations is a tendency to increase the perihelion distances of the objects; it is concluded that if the aphelion distance is about ten thousand units, or one-thirtieth of the distance to the nearest star, the perihelion distance is likely to be so much increased that few, if any, of such comets would come into the sphere of visibility from the earth. Some 2,000 units is estimated as the probable greatest aphelion distance of the comets that can be seen from the earth; for meteors the lower figure of 1,000 units is adopted. If such meteors date back to the origin of the solar system, estimated to have been some 3,000 million years ago, they would have approached the sun more than a hundred thousand times; the heat experienced is estimated as equivalent to about thirty thousand years of continuous heating to a temperature exceeding 0° C. This would, according to the author's estimation, suffice to deprive a stony meteor of all its helium. This research, which is of a novel character, was undertaken in connexion with the extensive meteor work initiated at Harvard by Prof. Shapley.

Spectral Types of Faint Stars. Kapteyn's plan of "Selected Areas" included the determination of the spectral types of as many stars as possible in each area. Part of this work of classification was undertaken by the Mount Wilson Observatory, and a list of 4,066 spectral types has now been published by Dr. Humason (*Astrophys. J.*, vol. 76, p. 224). These cover the first 115 areas of Kapteyn's plan, and include stars down to the 15th magnitude (photographic). The observations were made with a slitless spectrograph at the Newtonian focus of the 60 in. reflector, which gave spectra of 7·84 mm. length from $H\beta$ to $H\epsilon$. These spectra were classified by matching with plates of standard stars, the mean of three observations being adopted as the spectral type. The principal criteria used were the hydrogen lines, the [*H*] and [*K*] lines of calcium, the [*G*] band and the *M*-type bands. The only difficulties encountered were in distinguishing between types *F* and *B*, which strongly resemble each other in such small-scale spectra if they are not strong enough to show the [*H*] and [*K*] lines. In addition to the list of observed spectral types, the author includes some statistical notes, with frequency curves for each type in different regions and for all regions together.

Royal Society Mond Laboratory

THE new Royal Society Mond Laboratory (Fig. 1) which has been presented to the University of Cambridge by the Royal Society was formally opened on February 3 by the Chancellor of the University, Mr. Stanley Baldwin.

The ceremony was preceded by an official luncheon in Corpus Christi College, given by the Vice-Chancellor, Mr. W. Spens, who welcomed a large gathering representative of the Royal Society, the Department of Scientific and Industrial Research and most of the schools of physical science in Great Britain. After the luncheon, a meeting was held in the Arts School when the Cavendish Professor, Lord Rutherford, explained the purpose of the laboratory and gave an account of the early stages of the work of Prof. P. Kapitza, referring in particular to the great difficulties at the outset, when for a time it seemed almost impossible to construct coils which would not be disrupted by the large electromagnetic stresses developed during the experiments.

Sir Frederick Gowland Hopkins, president of the Royal Society, then formally presented the laboratory to the University. He referred to the connexion which has always existed between the Royal Society and the University, a connexion which has been particularly helped by the sequence of Cavendish professors who have also been presidents of the Royal Society. It was his privilege to convey this gift from an ancient but progressive scientific society to a still more ancient but no less progressive university.

Sir Robert Mond then gave a short address and spoke of the great interest his father, Dr. Ludwig Mond, had always shown in scientific research, an interest which was largely responsible for enabling Dewar's pioneer researches in low temperatures to be carried out and is now bearing further fruit in this gift, which the Royal Society has been able to make from the accumulated interest of the Ludwig Mond bequest. The Chancellor, in accepting the gift on behalf of the University, gave a brief account of the history of the work which has led to the construction of the Laboratory. After several years of preliminary experiments in the Cavendish Laboratory, Dr. Kapitza was able in 1925 to develop a method of producing magnetic fields of the order of 300,000 gauss by passing the heavy initial current from a short circuited alternator through a small coil. To obtain the large currents of the order of 15,000 amperes necessary for the work, a special alternator was required and its purchase was made possible by generous grants from the Department of Scientific and Industrial Research, which was farsighted enough to see the importance of the work and to support it during its infancy. The Department later provided the grant which enabled a liquid hydrogen plant to be constructed and thereby enabled cryogenic work to be taken up again in England after an interval of many years since Dewar's experiments.

The Chancellor reminded his audience that the greatness of a country in the eyes of the world and of history will be measured not so much by the size of its armaments or of its industries as by its permanent contributions to art, literature and science. Modern industry is becoming more and more dependent on the application of discoveries in pure science, and successful industrial research is ultimately dependent on the vigorous prosecution of research in pure science. Whilst as a statesman he would accept no responsibility for the social effects of any work which might come from the Laboratory, as Chancellor he welcomed the gift for the great addition which it makes to the facilities available for experimental physics in the University.

FIG. 1. Entrance to Royal Society Mond Laboratory

The new laboratory, designed by Mr. H. C. Hughes, stands in the courtyard of the Cavendish Laboratory. It has been fortunate indeed that soon after the gift of the Royal Society had been accepted, it became possible for the University to build new lecture rooms for the Department of Engineering, and so to clear away from the Cavendish site the old engineering workshops in which the School of Engineering in Cambridge was born, thereby enabling the site to be allotted to the new Laboratory. This close proximity of the Laboratory to its parent body, the Cavendish Laboratory, cannot fail to facilitate and invigorate the work of the Laboratory, since its work is, and must continue to be, mainly physical, whilst the provision of cryogenic facilities may well exert a marked influence on the future work of the Cavendish Laboratory.

Surrounded on all sides by high buildings, the Laboratory has been designed for the most part as a single storey block with a group of first floor rooms for offices at one end. The basic idea of the plan has been to separate and isolate, so far as possible, the research rooms from the heavy machinery which is necessary to the work of the Laboratory. The central hall shown in the plan (Fig. 2) is devoted to the main experimental apparatus of the Laboratory —the large generator which produces the very intense currents and its auxiliary apparatus. Near the generator in adjacent rooms are arranged the machine room, workshop and liquid air room. In these rooms great care has been taken to reduce the noise produced by the machinery at its source by the free use of asbestos sound absorbent; special precautions have been taken to prevent the transmission of noise through doors, and in addition, the steel frame of the building has been erected in two separate sections so that there can be no direct transmission of vibrations from the machine end to the research end of the Laboratory. The roofs of the two sections overlap and only lead aprons, a mortar joint filling and two insulating pads join the two sections. The result of these precautions has been very satisfactory, the noise of the machines and liquid air plant being practically inaudible in the rest of the laboratory.

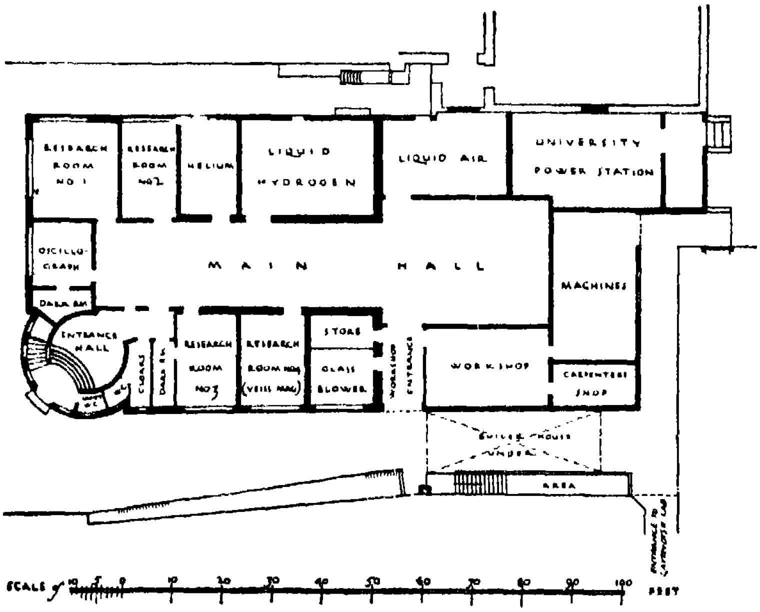

FIG. 2

The liquid hydrogen plant already described in NATURE (129, 224, Feb. 13, 1932) has been removed to the new Laboratory, the only change made being in the system of gas storage. In place of cumbersome oil-filled gas holders which are usual for this work, a very small gas holder is used having a capacity of about 1 cubic metre, the main volume of the gas being stored at 10 atmospheres pressure in hollow steel forgings, automatic pumping plant being installed to convey the gas from the storage cylinder to the gas holder as required. In this way it is hoped to minimise the diffusion of air impurities from the oil of the gas holders into the hydrogen, one of the most common sources of trouble in liquefaction work. A further advantage lies in the great reduction of space effected, and as a result it has been possible to house both a hydrogen and helium liquefaction plant in a room about 25 ft. × 18 ft. The compressors and storage system for the helium liquefaction are installed, and it is hoped to construct the liquefier within the next few months.

The six research rooms of the Laboratory open out of the main hall at the north end. Each research room has large plate glass windows with adequate dark blind arrangements; the walls are plain distempered brick with vertical wooden strips to provide fixing accommodation for apparatus; the rooms are heated by panel radiators fixed on the ceiling to economise floor space. An even temperature is ensured in all the research rooms, first by fitting thermostatically controlled valves to all radiators, and secondly by having an oil-fired boiler with thermostatic control of the water temperature.

In each room a concrete galvanometer foundation goes down to a depth of 10 ft. and heavy section earthing rods should ensure that independence of extraneous electrical disturbances which is so essential for magnetic researches. A cross-connexion switchboard in the main hall enables any one of five different machines to be connected to and controlled from any desired room; at the same time each room has available a separate switchboard on which are a 220 volt battery, four terminals which can be connected to any desired cells in a 110 volt battery, a three wire automatically regulated 110/220 volt D.C. supply, a four wire 3-phase A.C. supply and a galvanometer lamp supply. From the switchboard an overhead grid allows the supply to be conveyed neatly to any table in the room. Self-starting synchronous clocks have been installed in each research room in place of the half minute impulse clocks, to eliminate the magnetic disturbances which are apt to be introduced by the impulse type. All the synchronous clocks are fed from a central point near a master clock which is fitted with both synchronous and impulse dials, and a frequency change arrangement enables all the clocks to be actuated from this point should a failure of supply lead to stoppage. The master clock is also used to provide seconds impulses to any room if required.

Every advantage has been taken of the flexibility allowed by modern building materials to meet the special requirements of the Laboratory at the least possible expense. As a result, the average cost has been less than 1*s*. 3*d*. per ft. cube, of which 10 per cent was for special foundations. The main decorative features of the interior are the attractive modern furniture designed by the architect, Mr. H. C. Hughes, and the gay colourings of the pipes conveying the different services. The only decorative feature of the exterior is the crocodile rampant excised in the white bricks by Mr. Eric Hill. Of the many explanations of the significance of this carving, we may record one—to the sculptor at least it signifies "Science Devouring Culture". The exterior of the building has been faced with white Leighton Buzzard bricks; these together with the large plate glass windows and circular entrance give the building a modernist character, whilst at the same time its simplicity should enable it to be a harmonious neighbour to its very mixed surroundings.

International Congress of Scientific and Applied Photography[*]

THE first International Congress of Photography was held in Paris in 1889. Congresses followed at Brussels in 1891, Paris in 1900, Liège in 1905, Brussels in 1910, Paris in 1925, London in 1928 and Dresden in 1931. It is hoped to continue the meetings triennially and the next one will probably be held in America in 1934. The recently published report of the proceedings of the eighth Congress affords a very good view of the activities of the organisation.

Standardisation of photographic sensitometry has since 1925 been one of the principal objects of the Congress. National committees for dealing with this problem have been set up in Germany, England, France and the United States. After discussions and researches lasting over three Congresses, agreement has at length been reached on a photographic unit of daylight for the testing of such materials as are to be used in daylight. The standard approaches very closely the quality of mean noon sunlight at Washington, and intensities are to be expressed in visual candles. The standard light is comparatively easy to reproduce in the laboratory since it consists in a vacuum electric lamp operating at a colour temperature of 2,360° K. and corrected by means of a two-cell liquid filter of blue colour. The filter is one of a series worked out with great care by Messrs. Davis and Gibson of the Bureau of Standards at Washington and is easily prepared. In other details of the technique of sensitometry a series of recommendations has been drawn up. Thus the methods of obtaining the characteristic curves of photographic materials have been largely unified. The interpretation of the data is, however, not nearly so clear to define; the real meaning of photographic 'speed' is still a matter of great difficulty. The German section of the Congress is, however, making a bold attempt to standardise a method for the determination of commercial speed numbers. This will be very difficult because, although the standardisation of the methods of determining characteristic curves of photographic materials is now within sight, the derivation of 'speed' numbers from the curves is still a subject of acute controversy.

For cinematography the Congress also yields opportunities for achieving international standardisation in such matters as the dimensions and spacing of sprocket holes in film, the definition of the meaning of the term 'safety film', etc.

The chief interest of the Congress lies, however, in the scientific papers presented for discussion. It is interesting to watch the growth or decline of interest in various subjects from one Congress to another. The subject of sound-recording claimed only two short communications in the Congress of 1928. At the 1931 Congress, however, eight papers of considerable scientific importance dealt with various aspects of sound-recording. In 1928 the sound film was in its infancy, by 1931 it had grown out of recognition, indeed it has been said that the number of investigators studying this subject is four times as great as the number studying all other branches of photography. The exact number may be founded mainly on guess work, but the general truth of the statement probably stands.

For research in chemistry and physics, photography appears to serve the function of providing endless themes. It is worth noticing that several papers were communicated from various continental universities and technical institutes. Only two research papers were sent in from England; these emanated from laboratories maintained by the photographic industry. It may be suggested that workers in university laboratories would gain a great deal of inspiration by a careful study of the possibilities presented by photographic science as a field for research.

Electrolysis of Boron Hydrides

IN a communication to the November issue of the *Berichte der deutschen chemischen Gesellschaft*, Herren A. Stock and E. Wiborg discuss the mechanism of the complex changes whereby substitution of hydrogen by amino-groups takes place when solutions of boron hydrides in liquid ammonia are electrolysed. Two distinct reactions have been traced, namely, one which produces hydrogen as the only gaseous product and one which results in the liberation of hydrogen at the cathode and nitrogen at the anode.

These two reactions have been studied in detail. The former predominates for a time but gradually dies down until eventually it is completely replaced by the latter. This stage is indicated by the settling down of the current to a constant minimum value. Solid substitution derivatives can be recovered from the solutions by evaporation of the solvent. These solids were hydrolysed in order to determine their composition. Analysis of the results shows that the hydrogen which is liberated in the first reaction is due principally to chemical substitution of hydrogen by amino-groups but that this substitution is initiated and maintained by electrolysis of the boron hydrides. The other reaction is ultimately due to the electrolysis of ammonia, but as pure liquid ammonia is scarcely affected by the current, it is evident that in this case also some secondary factor has to be considered.

The authors have previously shown that boroethane, B_2H_6, acts as a dibasic acid and they are now able to trace the gradual cessation of the first or substitution-reaction to the diminution of acidity by the formation of inner salts of the amino-derivatives (after the manner of glycocoll). Some of these inner salts will still be sufficiently acidic to undergo further electrolysis and subsequent substitution, whilst others will be neutral and therefore resist further action. Thus the substitution reaction gradually fades out.

Again, the active factors in promoting the direct electrolysis of the ammonia (that is, the final reaction) are said to be the anions of the inner salts, since decomposition of ammonia is not observed in the early stages of the electrolysis. Boroethane gives rise to the compound $B_2H_4(NH_2)_2$ as the final product of substitution.

The compounds B_4H_{10} and $B_{10}H_{14}$ were also studied under similar conditions, when it was found that replacement of six and twelve hydrogen atoms respectively could be effected.

University and Educational Intelligence

CAMBRIDGE.—The Buildings Syndicate has recommended to the University that the plans for buildings for the Department of Zoology prepared by Mr. J. Murray Easton be approved and that Dove Brothers' tender of £72,363 for the work be accepted. If approval is given to this report at the earliest possible date, the first section of the new Zoological Laboratory should be ready for occupation by October 1, 1933 and the whole by October 1, 1934.

At Jesus College, Dr. H. Spencer Jones, formerly a fellow of the College, and recently appointed Astronomer Royal in succession to Sir Frank Dyson, has been elected to an honorary fellowship.

THE Royal Technical College, Glasgow, succeeded last session in fully maintaining its activities despite the continued depression in many of the industries in Glasgow and its neighbourhood. Statistics given in the recently published annual report show that the number of day students (897) falls short by less than one per cent of the number in the preceding year and evening students numbered 2,728, as against 2,880 in 1930–31. The very difficulties which the College has been called upon to face appear to have increased rather than diminished its vitality, and the financial position is satisfactory. Among the notable events of the year was the establishment of a series of bursaries to enable distinguished evening students of the College, whose higher education has been gained while they were at work during the day, to continue their studies by attendance at College day classes, thus helping to remedy one of the defects of the British system of technical education to which attention was directed in NATURE of December 24. Substantial progress was made with the erection of a five-foot diameter open-jet type wind tunnel, intended for the investigation of problems in general engineering as well as in aerodynamics. When completed, the installation will, it is anticipated, be unique in its range of applicability.

Calendar of Nature Topics

Commencement of Salmon Season

February 11.—"The trout and salmon, being in season, have . . . their bodies adorned, the one with such red spots the other with such black or blackish spots, as give them such an addition of natural beauty, as I think, was never given to any woman by the artificial paint or patches, in which they so much pride themselves in this age." (Walton, "The Compleat Angler".)

Walton is much less voluble than usual over the technicalities of angling in his discourse on the salmon. Probably his practical acquaintance with salmon fishing was limited. His account of salmon natural history, however, indicates the main lines of its life-history well enough, despite errors in detail such as August for the spawning month, and the notion that the growth "out of their lower chaps, not unlike a hawk's beak" develops after spawning is over. Apart from more precise determination of systematic relationships among the Salmonidæ, progress since Walton's day has consisted largely in elucidating details of salmon movements, reproduction and growth. The most notable modern contribution is the discovery and utilisation of the fact that valuable information may be deduced from examination of the scales. Migration or marking experiments which, practised on a considerable scale during the last few decades, have yielded much, are a modern development of what seems to be a fairly old practice. "Much of this has been observed by tying a ribbon, or some known tape or thread, on the tail of some young salmons which have been taken in weirs as they have swimmed towards the salt water, and then by taking a part of them again, with the known mark, at the same place on their return from the sea." (Walton.)

Salmon Disease

Increasing attention to fisheries, following on the interest aroused in fish hatching as a means of keeping up stock in rivers, brought 'salmon disease' into prominence. This disease, now known for about a century, is marked externally by growths of the fungus *Saprolegnia ferax*. Day ("British and Irish Salmonidæ", 1887) records it as epidemic in British waters since 1878, and suggests various causes predisposing to the infection, which he considered as normally present but "requires a soil suitable to its germination". Hume Patterson (Rep. Scot. Fish. Bd., 1903) showed the fungus masked a bacillus (*B. salmonis pestis*) the essential organism of the disease. There is still considerable though varying mortality among salmon from this cause and from time to time it has broken out in epidemic force.

Furunculosis

Furunculosis is a more serious disease and lacks the notable external sign of secondary growth of fungus. Essentially a general infection, at present nothing short of bacteriological examination of the blood of suspected fish can give a trustworthy diagnosis, although external lesions may in some cases indicate that the disease is probably present. Emmerich and Weibel (1894) isolated the causative organism (*B. salmonicida*) and their findings were confirmed and extended by Hofer (1904) and Plehn (1909–24) on the Continent; in Great Britain by Arkwright (1912), Horne (1928), and Williamson (1928–30). The disease has been known in Europe for some forty years. In the United States it came under notice rather later (Marsh, 1902). Widespread outbreaks occurred in 1909–11 in France, Switzerland, Austria and south Germany, where in 1909, 25 Bavarian rivers held diseased fish. In 1911 furunculosis reached the south-western English rivers; less than two years after there was an outbreak in Ireland (River Liffey). Since then the disease has been reported in many British rivers. A severe outbreak among Kennet trout in 1924 prompted renewed inquiry into the origin and spread of the disease. In 1926 the finding of 459 dead salmon in the upper waters of the Tay, in what would appear to be an exceptionally favourable environment for salmon, attracted the attention of the Scottish Fishery Board to the disease, which has since appeared in many widely separated Scottish rivers. In 1929 a Furunculosis Committee was appointed by the Minister of Agriculture and Fisheries and the Secretary for Scotland and in the following March an interim report was issued. The Committee found the probable immediate origin of the disease to be fish farms, whence the bacillus may be carried to different rivers by apparently healthy trout distributed for stocking purposes. *Unhampered importation of supplies* from the Continent by such farms, as has occurred freely in the past, provides an easy route for the transmission of infected foreign fish.

That the English outbreak of 1911 should have followed the severe epidemics in Europe in 1909–11 is very suggestive. Transmission by casual migrants from Continental to British rivers must be excluded in view of the low viability of *B. salmonicida* in sea water (Williamson, 1928). It is therefore extremely likely that furunculosis is another case where the incautious introduction of livestock from abroad has done serious harm to the home fauna.

St. Valentine's Day. The Beginning of Spring

February 14.—Several English and French proverbs associate the beginning of spring with St. Valentine's day, when "winter's back breaks". Long-period averages for London confirm these sayings, showing that after remaining almost constant throughout January and the first half of February, the temperature begins to rise about the middle of the latter month. Persistent frosts rarely continue unbroken after this date, and even if the nights remain cold, the increasing power of the sun's rays is noticeable in a midday thaw. The crocus is expected to blossom about February 14, and is dedicated to St. Valentine.

Progress of Oceanography

On February 14, 1779, Capt. James Cook, F.R.S., was murdered by the natives of Owyhee, and the world thus lost at the early age of fifty-one years its greatest marine explorer and navigator, and one who is now universally acclaimed as the founder of the science of oceanography. On the same date, nearly one hundred years later, was made one of the most fruitful hauls of the *Challenger* Expedition, the results of the world-wide collections of which form the main basis upon which modern oceanography is built, and have dispelled for all time the belief that the deepest parts of the ocean are uninhabitable.

H.M.S. *Challenger*. February 14, 1876. Lat. 37° 17′ S.: long. 53° 52′ W. Station 320 (Sounding 407). Falkland Islands to Rio de la Plata.

"At 11.30 a.m. commenced heaving in trawl, which came up at 12.30 p.m., containing a little mud, five or six phosphatic concretions, and numerous specimens. This was one of the richest hauls made during the cruise."

"Excluding Protozoa, nearly 500 specimens of invertebrates and fishes were obtained at this Station, belonging to about 127 species, of which 103 are new to science, including representatives of 19 new genera; 80 of the new species and 6 new genera were not obtained elsewhere."

Societies and Academies

London

Royal Society, Feb. 2. J. C. McLennan and R. Turnbull: The ultra-violet absorption bands of xenon. The characteristic features of the two absorption bands in the neighbourhood of the resonance lines λ 1469·6 A. and λ 1295·6 A. can be explained by supposing them to be due primarily to absorption occurring during atomic collisions, when the energy levels of the colliding atoms were perturbed by their mutual interactions. At the lower pressures, mainly two-body collisions are effective, but at pressures above 90 mm. of mercury and at room temperature, collisions between three or more atoms occur frequently enough to affect appreciably the absorption. A comparison of the absorption bands at λ 1469·6 A. and λ 1295·6 A. reveals that with xenon, two-atom aggregates involving one atom in the $1\ P_1{}^0$ state are less stable than two-atom aggregates having one of the constituent atoms in the $3\ P_1{}^0$ state. D. M. Newitt and A. M. Bloch: The slow combustion of ethane at high pressures. In the slow combustion of ethane-oxygen mixtures of composition 85–90 ethane with 15–10 per cent oxygen, at high pressures, intermediate products, representing the six possible 'hydroxylation' steps whereby the ethane molecule is oxidised, have been isolated. At 100 atmospheres pressure, upwards of 60 (and in one case more than 70) per cent of the carbon of the ethane burnt survived as condensable and water-soluble intermediate products. Ethyl alcohol and/or acetic acid predominated among the surviving intermediate products but, in addition, considerable quantities of methyl alcohol, acetaldehyde and steam were always present together with smaller amounts of formaldehyde and formic acid. The effect of increasing the initial pressure of the reacting medium was in general to favour the survival of ethyl alcohol, acetaldehyde and acetic acid (that is, of products formed without any rupture of the ethane molecule).

Geological Society, Dec. 21. L. Hawkes and Hilda K. Hawkes: The Sandfell laccolith and 'Dome of Elevation'. Sandfell—a hill of rhyolitic oligoclase porphyry intruded into the plateau basalt series on the south side of Faskrudsfjord, eastern Iceland—is a laccolith which in form, relationship to the country rocks, and exposure, is comparable with the type intrusions of the Henry Mountains. The thickness of the original cover can be determined with greater precision than has hitherto been possible for such bodies, and it can be demonstrated that intrusion was accompanied by a doming at the earth's surface. The northern junction is mainly a faulted one, and the laccolith is asymmetric. S. Smith (with notes on fossils by C. J. Stubblefield): The occurrence of Tremadoc shales in the Tortworth Inlier, Gloucestershire. Hitherto the Tortworth Inlier has been considered as entirely of Silurian age, but recently Tremadoc fossils were found by one of the authors in the soft bluish-grey shale which forms much of the northern part of the Palæozoic outcrop. The Tremadoc rocks, for which the name 'Breadstone shales' is proposed, occupy the entire width of the inlier between Purton and Mobley and *cover an area of approximately* 3½ square miles. They provide the most southerly exposure of Cambrian rocks in Britain. Their outcrop lies nearly 30 miles south of that of the Bronsil shales of the Malvern region. A. D. N. Bain: The younger intrusive rocks of the Kudaru Hills, Nigeria. The members of the series present in these hills consist of a mass of cone-sheets and dykes surrounding pyroxene-fayalite-, riebeckite-, and biotite-granites, the riebeckite-granite forming the main intrusion. The earliest member is a very large cone-sheet consisting of a unique rock type, a pyroxene-fayalite-quartz-porphyry. The field work definitely establishes two swarms of minor intrusions, one coming before the main granites and the other and more numerous swarm, after them. The whole group has the form of an inverted cedar-tree laccolith or chonolith.

PARIS

Academy of Sciences, Dec. 27 (195, 1337–1440). Jules Drach : The integration by quadrature of a class of differential equations : $d^2y/dx^2 = F(x, y)$. A. Cotton and M. Schérer : The magnetic rotatory dispersion of a coloured diamagnetic compound, thiobenzophenone. These determinations were carried out with the liquid film only 0·13 mm. thick. For this diamagnetic liquid the anomalies of the magnetic rotatory dispersion were quite clear on both sides of the absorption band, but do not show the same characters previously noted in the case of cobalt chloride. The work will be continued with higher magnetic fields. C. Matignon and M. Séon : The action of steam on methane. Studies of the effects of different catalysts on the course of the reaction $CH_4 + 2H_2O = CO_2 + 4H_2$. Zirconia proved to be the best catalyst. Gabriel Bertrand and L. Silberstein : The importance of sulphates as manure. Laboratory experiments show that the introduction of a certain proportion of combined sulphur in an assimilable form is necessary. The use of potassium and ammonium sulphates in the field is suggested as desirable. Jean Cabannes : The Raman spectrum of the SO_4 ion in gypsum. A. Bigot : The rôle of solifluxion in the morphogeny of the hills of Normandy and the Maine. Paul Vincensini : The focal points of circles of a congruence. Georges Giraud : Non-linear equations of the elliptic type. General theorem and application. Soula : Integral equations of the first species with fixed limits. Juljusz Schauder : Partial' differential equations of the elliptic type. Herman Auerbach : Limited groups of linear substitutions. Carl A. Garabedian : The thick rectangular plate, uniformly loaded, the two opposite edges of which at least are supported. Maurice Golaz : Remarks on the viscosity of water. Jean Louis Destouches : Remarks on the theory of superquantification. Max Serruys : The localisation of the phenomena of detonation. Experimental study of knocking in an internal combustion motor. Antonio Cabreira : The variation of the orbit and velocity of Halley's comet and its distance from the planets causing the perturbations. Th. De Donder : The linearisation of any (ds^2). A. Hautot : The structure of the $K\alpha$ line of carbon. G. A. Boutry : The design of a low-frequency amplifier for the photoelectric cell. P. Fourmarier : The action of a magnetic field on a gas-filled photoelectric cell. F. Gallais : Silver iodomercurate. From measurements of the coefficient of magnetisation the existence of the complex compound Ag_2HgI_4 is proved, agreeing with the conclusions of J. Ketelaar based on X-ray diagrams. L. Palfray, S. Sabetay and Mlle. Denise Sontag : The action of various dehydrating agents on primary phenylethyl alcohol. When dehydration takes place, styrolene is formed in preference to the ether oxide. Paul Fleury and Jacques Lange : The oxidation of the acid alcohols and the sugars by periodic acid. This reaction appears to be specific for the α-diols. L. and H. Longchambon : The vanadinite from Hérival (Vosges). Mlle. Henriette Alimen : The palæontological bases of a subdivision of the Stampian in the Paris basin. G. Delépine : The extension of the Palæozoic seas in Asturia (Spain). Mlle. S. Gillet : An attempt at the classification of the upper Miocene and the lower Pliocene in Roumania. Transylvania and the Banat. D. Schneegans : The subdivisions of the Ubaye sheet in the Morgon massif (French Alps). F. M. Bergounioux : The place of the Trionyx in the classification of the chelonians. J. Coulomb : Researches on the magnetic anomaly at the summit of the Puy de Dôme. Idrac : Researches on the submarine phenomena of the bay of Villefranche-sur-Mer. Pierre Frémy : Living Cyanophyceæ in the thallus of *Codium*. A. Vladesco : The first partitions of the zygote in the leptosporangiate ferns. Mlle. Dzung Tsin Wang : Some observations on *Ustilago violacea*. E. Michel-Durand : The nitrogen, sulphur, phosphorus and potassium of the leaves of *Prunus laurocerasus* at the moment of their fall. E. Fischer-Piette, Roger Heim and Robert Lami : Preliminary note on a bacterial disease of *Zostera*. Léon Bertin : The anatomical bases of the classification of the apodal fishes belonging to the sub-order of the Lyomers. Emile F. Terroine and Mlle. Gilberte Mourot : The formation of puric compounds at the expense of protein material in endogenous nitrogen metabolism. Fernand Mercier and J. Balansard : Chemical and pharmacodynamical researches on the cardiotoxic principles of *Cryptostegia madagascariensis*. H. Labbé and M. Rubinstein : The action of adrenaline on the nitrogen exchanges. James Basset and M. A. Machebœuf : The study of the biological effects of ultra-pressures. Resistance of bacteria, diastases and toxins to very high pressures. M. and Mme. G. S. Adair and M. and Mme. J. Roche : Researches on the molecular weight of globin from various hæmoglobins. Ch. Dhéré : The tegumentary porphyrin of *Lumbricus terrestris*. S. Turchini : Remarkable effects of diathermo-coagulation in cancers of radiobiologists attacked by radiodermatitis.

GENEVA

Society of Physics and Natural History, Dec. 1. G. Tiercy : The variation of ionisation and the spectrum variation of some Cepheids. The extreme spectra correspond to the extremes of ionisation and the maximum ionisation is a little ahead of the light maximum, whilst the minimum of ionisation is ahead of the light minimum. E. Cherbuliez and Fr. Meyer : New researches on casein. Following up their earlier work, the authors conclude that casein from cow's milk is a mixture of at least four constituents which have been isolated, and the proportion of which in casein is not constant. R. Wavre : New examples of polydromes of prolonged Newtonian potentials. H. Lagotala : (1) Borings in the marly limestones of Renéville (French Congo). A description of the formations met with in the course of five borings, one of which gave the composition of the strata over 95 metres. The marly limestones found at the levels of schists (micaceous, grits, etc.) belong to the formation of the Niari limestones (schist-limestone series of Delhaye and Sluys). (2) Concerning the stratigraphic scale of the Niari limestones. It is impossible to utilise the divisions accepted by Delhaye and Sluys, and later by Babet, for the subdivision of the Niari limestones. In fact, the layers which should serve as a basis of reference are not constant in their facies. The author confines himself to establishing two groups, the lower ending with the appearance of the oolitic facies, following on a marl or clay facies. P. Balavoine : Contribution to the tetrafluoride test. By the action of water on silicon fluoride, there is not only formation of silica, since, carried out in contact with glass, the reaction also causes corrosion of the glass. C. Dallwick : Presentation of a map produced by the projection of the sphere on the icosahedron.

Forthcoming Events

Saturday, Feb. 11

SCHOOL NATURE STUDY UNION, at 2.30—(at Botanical Theatre, University College, Gower Street, W.C.). Annual Conference. At 3—Sir Frank Dyson: "Astronomy—Old and New".

Monday, Feb. 13

ROYAL GEOGRAPHICAL SOCIETY, at 5.—A. C. O'Dell: "The Urbanisation of the Shetland Islands".

UNIVERSITY COLLEGE, LONDON, at 5.—Dr. H. R. Ing: "Chemical Structure and Pharmacological Action" (succeeding lectures on Feb. 20, 27, March 6, 13 and 20).

UNIVERSITY OF LEEDS, at 5.15.—Prof. J. Barcroft: "The Evolution of the Body as a Milieu Adequate for the Mind".

INSTITUTION OF ELECTRICAL ENGINEERS (MERSEY AND NORTH WALES CENTRE), at 7.30—(Faraday Lecture at the Central Hall, Renshaw Street, Liverpool).—Prof. J. T. MacGregor-Morris: "Lightning, and how the Engineer deals with its Effects" (to be repeated before other Sections).

Tuesday, Feb. 14

ROYAL INSTITUTION, at 5.15.—Sir William Bragg: "The Analysis of Crystal Structure by X-Rays: A Review of the Work of Twenty Years" (succeeding lectures on Feb. 21, 28 and March 7).

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, at 8.30.—Prof. J. A. Gunn: "The Search for New Remedies".

Wednesday, Feb. 15

ROYAL METEOROLOGICAL SOCIETY, at 5.15—(Presidential Address).—Prof. S. Chapman: "Atoms, Molecules and Atmosphere".

UNIVERSITY COLLEGE, LONDON, at 5.30.—I. C. Gröndahl: "Oslo and its Environs" (succeeding lectures on Feb. 22 and March 1).

UNIVERSITY COLLEGE, LONDON, at 5.30.—J. Ross: "The Work of the Bristol Public Library".

ROYAL SOCIETY OF ARTS, at 8.—Capt. Harold K. Salvesen: "Modern Whaling in the Antarctic" (Film).

Thursday, Feb. 16

UNIVERSITY OF LONDON, at 5—(at the London School of Economics).—A. W. Street: "The Marketing of Agricultural Produce" (succeeding lecture on Feb. 23).

LONDON MATHEMATICAL SOCIETY, at 5.—Prof. P. A. M. Dirac: "The Relation between Classical and Quantum Mechanics".

ROYAL INSTITUTION, at 5.15.—A. R. Hinks: "Geography in the Public Service" (succeeding lectures on Feb. 23, March 2 and 9).

CHEMICAL SOCIETY, at 8.—Discussion on "The Raman Effect in Relation to some Chemical Problems", to be opened by Dr. J. J. Fox.

LINNEAN SOCIETY—(Hooker Lecture). Sir William Wright Smith.

Friday, Feb. 17

INSTITUTION OF CHEMICAL ENGINEERS, at 11.—Eleventh Annual Corporate Meeting. At 11.45, The Right Hon. the Viscount Leverhulme: "Chemical Engineering and the Soap Industry".

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—(Annual General Meeting).

INSTITUTION OF MECHANICAL ENGINEERS, at 5.30—(Annual General Meeting).—F. R. B. Watson: "The Production of a Vacuum in an Air Tank by Means of a Steam Jet".

Saturday, Feb. 18

ROYAL INSTITUTION, at 3.—Lord Rutherford: "Detection and Production of Swift Particles".

Science in the Schools

THE recent report on the School Certificate examinations conducted in England and Wales* is an illuminating and an alarming document. It reveals the grave fact that an examination originally "designed to test the results of the course of general education before the pupil begins such a degree of specialisation as is suitable for Secondary Schools" has petrified the curricula of the schools in a mould that eliminates almost completely any individual efforts at originality or initiative. The danger was foreseen, for when the scheme was begun, some fourteen years ago, it was laid down as a cardinal principle that "the examination should follow the curriculum and not determine it". What apparently was not foreseen was the impossibility of establishing a general examination with a limited syllabus, yet preventing schools from working almost wholly to that syllabus. It is true that there are eight distinct bodies conducting School Certificate examinations, but the greatest pains have been taken to make all eight examinations as like as so many peas, until now no one could distinguish between them by a mere inspection of the questions.

In the summer of 1931, 66,909 candidates sat for the School Certificate examination. Assuming four years as the average time of preparation, it follows that the educational course of a quarter of a million boys and girls in England and Wales is being directly moulded by the requirements of eight slight variants of the same syllabus. The candidates are by no means drawn from the State-aided schools alone ; on the contrary, the public schools present a contingent that forms perhaps 25 per cent of the total entry. The question whether this application of mass-production to education is not likely to have extremely pernicious results is consequently a very pertinent one, demanding the immediate and careful attention of everyone who has the interests of the children of the country —and therefore the future of the country itself— at heart.

Examinations are not necessarily an evil. They serve purposes that could not be adequately fulfilled by any other means, and a body of competent examiners can form a very accurate, and thus very useful, estimate of a candidate's attainments and ability. It is, however, clearly undesirable that the educational system of the country should be so ridden by a stereotyped examination that, to all intents and purposes, every boy and girl at sixteen has learned exactly the same things, taught in exactly the same way. It is particularly deplorable that the public schools, where experiments in education are most easily possible, and where, in the past, great educational reforms have in fact been initiated, should have fallen so completely under the spell of the School Certificate.

---

* The School Certificate Examination : being the Report of the Panel of Investigators appointed by the Secondary School Examinations Council to inquire into the Eight Approved School Certificate Examinations held in the Summer of 1931. (London : H.M. Stationery Office, 1932.) 2*s*. 6*d*. net.

Admittedly their position is difficult. The possession of a School Certificate is of great value to many boys (especially since it may be, what it certainly ought not to be, a matriculation qualification), and of vital importance to some; so that if parents require public schools to prepare their sons for this examination, the schools must either acquiesce or lose the fees. The latter, under present conditions, they can ill afford to do, and so the fetters become more and more firmly riveted. It is a depressing thought that the great schools of England should be judged, in any degree, upon the lengths of their respective lists of successful candidates at the School Certificate; but there is growing evidence that judgment is frequently passed upon these very grounds. Freedom to follow new ideas is essential to the health of education, and if the public schools are to remain hampered by the rigid demands of the School Certificate syllabus, our best educational laboratories will become stultified and unfruitful.

For the moment, however, we must face the unhappy fact that the School Certificate is the predominating influence in secondary education. Until that influence can be reduced to the useful minimum originally anticipated, it behoves the country to ensure that the examination is brought to the highest degree of efficiency, the broadest degree of sanity, and the lowest degree of pedantry in syllabus, that can be achieved; though there are many who doubt whether an external examination of any kind, however excellent, is desirable at the early age of sixteen. The present report, drawn up by a panel of investigators composed of several of H.M. inspectors of schools and representative head-masters, head-mistresses and other teachers, while disturbingly complacent over the problem as a whole, offers many suggestions for improvement in detail and is reassuring upon the efficiency of the examining bodies. Upon the last point, indeed, no one has any serious doubt. The machinery is well designed and runs smoothly; examiners are chosen with care and are properly coached in their duties; cases of injustice to candidates are so rare as to be practically non-existent; and the schools are taken into free and constant consultation. There are, inevitably, technical details that require adjustment, and the panel has many observations to make on such matters, but the general impression left by the report is that the administrative and examining sides of the system—one had almost written the industry—leave little to be desired.

The real difficulties become apparent only when we pass from the machinery to the syllabuses. Though there is a good deal that might be said upon the other subjects of the examination, in these columns we shall deal solely with the problem of science—partly because it is our proper sphere, but chiefly because the place of science in education is still so largely a matter of controversy that School Certificate science needs very close consideration. The cardinal fact, always to be borne in mind, is that the School Certificate syllabus represents the whole of the training in science that the vast majority of middle and upper class citizens are likely to receive. We must inquire whether the work is oriented towards satisfactory objectives and whether it is pursued by adequate methods. The country is fortunate in possessing two such enthusiastic and able bodies of teachers as the Science Masters' Association and the Association of Women Science Teachers, but the grip of the School Certificate is so firmly set upon the schools that every public and secondary school master or mistress must work within narrow and well-defined limits. Consequently, though the methods of science teaching may be sound, the position cannot be regarded as satisfactory unless the examination limits are wide enough to admit the full objectives, and unless the objectives themselves are adequately conceived.

We confess that, in our opinion, the proper aims of school science do not appear to have been fully realised either by the panel of investigators or by the examining bodies. The importance of science to a good citizen, *qua* citizen, is duly emphasised, as in a modern system of State education it could scarcely fail to be. The value of scientific knowledge to a man or woman, as an aid to health and as a factor in earning a livelihood, is also not forgotten. But of the joy of science for its own sake, the intellectual joy that gives pleasure of a permanent and unequalled quality, the School Certificate (O shade of Aristotle!) has apparently never conceived. Also, except in so far as it is one among many essential social activities, the future of science is completely ignored. It has not yet occurred to our educational arbiters that, if the world is to continue to exist, the well-being and progress of science must be assured. We should like to have seen a bold gesture on the part of the investigators, either completely remoulding the present syllabuses in science, or insisting upon a radically different method of examining upon them. Intrinsically, perhaps, the syllabuses are moderately satisfactory, and in some branches even good; but the questions set—which determine the teaching—are far too academic. History shows us unmistakably that scientific philosophy is late in flowering; and if we may take the maxim as roughly true that the intellectual development of the child recapitulates that of the race, we shall see the folly of asking a normal boy or girl of sixteen to deduce Gay-Lussac's law from Avogadro's hypothesis, or to answer similar questions on recondite theory. If an external, uniform examination is to be inflicted upon young children, then, so far as science is concerned, the work should be much more largely observational and descriptive, a wider choice of subjects should be allowed, and the questions should be far less technical.

The panel takes a step in this direction—a step that we welcome—by recommending the establishment of an obligatory paper on elementary science, covering an extensive field, followed by additional papers on physics, chemistry and biology which would be optional. The basic idea of this scheme is admirable, and, with reservations, we hope that it may be adopted. It would result in a broader appreciation of science, and would attract many children who are frankly bored or dazed by the more purely academic courses at present offered them. But it is easy to foresee certain difficulties that will have to be overcome if the step in advance is not to metamorphose into a retrograde movement. The most serious of them is to prevent the danger that a course in elementary science may develop into a shallow smattering of more or less disconnected topics, in which all the peculiar value and character of science is lost. A second difficulty lies in finding teachers properly equipped for a scheme of this kind, for it seems clear that the course could not fully attain its purpose if different parts of it were taught by different men; while unfortunately many science teachers are not well informed in branches of science other than their own. A third difficulty, which is, however, a matter for the administration, will arise from the fact that Higher Certificate science will need to be reorganised if a School Certificate candidate can obtain a pass in science on the proposed elementary paper.

A final point of importance in the recommendations in the report is the suggestion that practical examinations be dropped at the School Certificate stage. Some of the examining bodies have already taken this course, and the panel of investigators thinks that the others might well follow their example. If the authorities are satisfied that the practical work in schools will not suffer by the absence of a practical examination, we have no adverse comment to make; but we may perhaps remind them of the long and strenuous fight that had to be made to put school practical science on a sound footing, and we trust that they are not proposing to throw away a valuable asset.

Evolution of the Microscope

The History of the Microscope: Compiled from Original Instruments and Documents, up to the Introduction of the Achromatic Microscope. By Dr. Reginald S. Clay and Thomas H. Court. Pp. xiv+266. (London: Charles Griffin and Co., Ltd., 1932.) 30*s*. net.

THE story of the development of any scientific instrument is an interesting one, but this is especially so when the result of the development is so universally known and used as the microscope.

It is impossible to imagine the modern scientific laboratory without this invaluable tool. The pathologist, to whom the clinician refers for help in a diagnosis, the bacteriologist, studying the purity of our foods, and the physicist, making measurements of fundamental importance, all depend on the efficiency of a system of lenses grouped together to magnify the object which is being observed. The microscope has become such a commonplace that we are apt to forget its importance, and its origin.

The book under review has been prepared by two men particularly well equipped to write an authoritative treatise on the history of the microscope. Both of them are known as collectors of old optical instruments. Mr. T. H. Court, the generous donor of a unique collection of scientific instruments to the Science Museum, South Kensington, has for many years collected not only instruments but also books, catalogues, and trade-cards which have thrown great light on many obscure points in connexion with the manufacture and sale of the microscope. Dr. R. S. Clay, possessing not only a valuable collection of microscopes but also of optical literature, has brought to his task a knowledge of optics which is authoritative.

The microscope is not old as compared with the astrolabe or some of the instruments devised for determining the position of the heavenly bodies. The single lens, however, is undoubtedly the oldest optical instrument, and from combinations of such lenses the telescope and the microscope were evolved.

The authors have examined many early references, and show that the credit for the invention both of the telescope and microscope must be given to the Dutch spectacle-makers, Hans Jansen and his son Zacharias. The first instruments were made about 1590, or at the beginning of the seventeenth century, the period which saw the birth of physical science as we understand it. The knowledge of the possibilities of the microscope soon spread, and we learn that Cornelius Drebbel (the mathematical tutor to James I) was making microscopes from 1619 to 1623, although they were probably single-lens instruments. The Drebbel instruments became well known, and the value of the instrument for scientific research may be said to date from this time.

In 1665 Robert Hooke published the "Micrographia"—a book which fills one with wonder at the originality and variety of the ideas contained in it. It includes many copper-plate illustrations of objects which Hooke had drawn in great detail with the aid of the microscope, such as the edge of a razor, the point of a needle, sections of plants, moulds and insects. Hooke described in some detail the construction of his microscope. The objective consisted of a double-convex lens of short focal length, mounted in a cell with a pin-hole diaphragm close to the lens; the eye-piece consisted of a large field-glass and an eye lens. For some time it was thought that Hooke had suggested the use of the field lens, but there is little doubt that this was due to Monconys, who in his "Voyages", published in 1665, gave a specification of a microscope he had had constructed by Campani in 1660, which included a field lens. There is no doubt that microscopes fitted with field lenses were being sold in London in 1662. Helvelius, who had a great admiration for the English microscope, added in 1673 to an English-made instrument, the focusing screw, and a fine adjustment for focusing the object—a great advance on the cumbersome method of sliding the vellum tubes one inside the other.

Marshall may be regarded as the first great English optician. His microscopes were well constructed and in great demand. He revived, if he did not re-invent, the slow-motion focusing adjustment of Helvelius, and fitted a ball and socket joint at the bottom of the pillar so that this instrument could be inclined at a convenient angle for observation. He was the first to fit a condensing lens under the stage of the microscope for the better illumination of transparent objects. A set of six objectives of varying magnifying powers were generally supplied in a drawer fitted in the base of the instrument.

The circulation of the blood had been discovered by Harvey in 1628, and thus its demonstration in the tail of a fish or in the web of a frog's foot was of great interest to users of microscopes. Marshall actually advertised his instrument as the "New Invented Double Microscope for Viewing the Circulation of the Blood". The possibility of being able to demonstrate the circulation of the blood with a microscope remained for more than a century one of the greatest selling points of the instrument. Accessories for holding the frog or fish were included in the majority of microscope outfits.

The next great step in the development of the microscope was due to Hertel. In a book published in 1716, he described in detail an instrument which contained some important features, the chief of which was a plane mirror for illuminating transparent objects; he also invented a screw, and a ruled micrometer—three inventions of such importance that his name should be remembered with gratitude. About fourteen years later, Culpeper introduced the concave mirror mounted on gimbals and placed in the optic axis of the instrument. This, as the authors point out, was one of the greatest inventions made in connexion with the microscope, combining as it does the functions of the reflector and condenser. The placing of the mirror permanently in the optic axis had a great influence in perpetuating the rigid upright axis. In 1744, Cuff made the vertical type of microscope completely in brass, and reverted to the Helvelius method of focusing which had been so strangely neglected for seventy years.

Benjamin Martin, 1704–82, had a great influence on the development and use of the microscope.

He published a large series of popular handbooks on physics, and particularly on optical instruments. Judging by the number of these books that are to be found in the catalogues of second-hand booksellers, they must have had a large circulation. He was responsible for the design of the 'drum' microscope which became so popular, being made in large numbers on the Continent. The two George Adams, father and son, made microscopes of outstanding quality, and they vied with Martin in making advances in the design and construction of their instruments. In addition to their mechanical abilities, they both had marked literary gifts which were shown in a series of textbooks. The father published the first edition of his "Micrographia Illustrata" in 1746, and the son entirely re-wrote the work in his "Essays on the Microscope" published in 1787. In his 'Prince of Wales' microscope, Adams, Sr., mounted the instrument on trunnions, and fitted a rack and pinion coarse-adjustment, and a screw fine-adjustment. For convenience in working, and for rigidity, this instrument was far ahead of its competitors. It is not easy to understand why the trunnion form of mounting was not adopted. It had to wait for nearly fifty years before it was re-introduced; it is now used universally in all first-class instruments.

Space has not allowed of any discussion on the simple microscope. This is not for want of material in the book, because the authors have given us in Chap. iii (45 pages) an interesting story of Leeuwenhoek's instruments, and the development of the simple instrument. Chap. x, dealing with solar and scroll instruments, brings home vividly to the reader the disadvantages of sunlight as a source of illumination as compared with the modern electric lamp.

A list of instrument makers, with brief biographical notes, contains information which must have taken a great deal of patient research to obtain. This research is an outstanding feature of the book.

A few errors and omissions have been noted, and should be corrected in a second edition. Page 118—the name Baker is incorrect, it should be Barker (see p. 229): Page 156—the date of the invention of the micrometer by Gascoigne was 1638 not 1743: Page 183—for Milsdoerffer, Mitsdorffer should be read: Page 199—the title of the book by Adams, Jr., was "Essays on the Microscope" and not "Micrographical Essays": the name of John Cuff should be inserted in the list of instrument makers.

It is not easy to clothe the dead bones of the history of an instrument and to make them tell a living story. This the authors have succeeded in doing in a way which evokes admiration. Unfortunately they finish the story of the microscope before the introduction of the achromatic lens. It is to be hoped that some day, in a succeeding volume, they will be able to bring the narrative up to modern times.

ROBERT S. WHIPPLE.

A Concise Theoretical Physics

Lehrbuch der theoretischen Physik. Von Prof. Dr. Georg Joos. Pp. xvi+644. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1932.) 26 gold marks.

THE author has set himself the considerable task of covering in six hundred pages the whole of theoretical physics, including modern developments, and it may be said at once that he has been extraordinarily successful in conveying, in the brief space at his disposal, the essence of the theories which he exposes. While the book is necessarily mathematical, no calculation of any importance is ever carried out without introductory discussion in which the assumptions and their meaning are carefully set forth. It is, in fact, just such a treatment as the practical physicist requires, and the exemplary self-control, such as is not always exercised by his countrymen, with which the author has confined himself to essentials, has not only enabled him to pack his matter into one volume but has also given that volume a very attractive unity.

The first third of the book is taken up by a mathematical introduction, quite simply written, in which the author expounds the vector calculus and certain matters not usually dealt with in ordinary courses of elementary mathematics, and by a section on mechanics, covering elementary elasticity and hydrodynamics and leading up to relativity. The next section, which can be roughly described as dealing with classical electricity, includes, as a development of electromagnetic waves, all that the book has to say of light. It is followed by a treatment of the atomic aspect of electricity, in which the author starts with the conduction through liquids, and then proceeds to gases and finally metals. He takes dielectrics and magnetism together, a good example of the method in which he has frequently abandoned traditional arrangement in favour of, from the mathematical point of view, a more logical grouping. The theory of heat he treats first from the thermodynamic, then from the statistical point of view, the latter leading up to radiation and the new statistics of Fermi and Bose. His last section, on the structure of the atom, closes with a brief treatment of wave mechanics.

The author very justly says in his preface that the book is not a mountain railway, to bring the reader without effort to the peaks, but rather a mountain guide, which leads the reader to places from which he can get a good view of the peaks. It will not make easy reading for a student approaching the subject for the first time, but it is a most excellent book for him to study with a teacher, or for him to use in order to complete and consolidate preliminary knowledge. For the more experienced student and for the teacher of physics rather than of applied mathematics, it is in every way to be commended. E. N. da C. A.

Descriptive Zoology

Handbuch der Zoologie: eine Naturgeschichte der Stämme des Tierreiches. Gegründet von Prof. Dr. Willy Kükenthal. Herausgegeben von Dr. Thilo Krumbach.

(1) Bd. 2: Vermes Amera, Vermes Polymera, Echiurida, Sipunculida, Priapulida. Lief. 11. Pp. 257–416. 18 gold marks.
(2) Bd. 2, Lief. 12. Pp. 32 + 64. 12 gold marks; Lief. 13. Pp. 65–212. 18 gold marks.
(3) Bd. 2, Lief. 14. Pp. 160. 20 gold marks.
(4) Bd. 3, Hälfte 2: Chelicerata, Pantopoda, Onychophora, Vermes Oligomera. Lief. 1, Teil 3. Pp. 160. 20 gold marks; Lief. 2. Pp. 32 + 48. 10 gold marks; Lief. 3. Pp. 32 + 64. 12 gold marks.
(5) Bd. 6: Acrania (Cephalopoda), Cyclostoma, Ichthya, Amphibia. Hälfte 2, Lief. 1. Pp. 112. 15 gold marks; Lief. 2. Pp. 113–208. 12 gold marks.
(6) Bd. 7: Sauropsida, Allgemeines; Reptilia; Aves. Hälfte 1, Lief. 1. Pp. 128. 16 gold marks.
(7) Bd. 7: Sauropsida, Allgemeines; Reptilia; Aves. Hälfte 2, Lief. 6. Pp. 545–656. 14 gold marks.
(Berlin und Leipzig: Walter de Gruyter und Co., 1930–1932.)

VOL. 1 of this work, which is to consist of seven volumes, was completed nearly seven years ago and the first half of Vol. 3 in 1927 and of Vol. 4 in 1930. Most of the other volumes are making good progress except the fifth volume (Mollusca, Echinoderma and Tunicata) three parts of which, completing the account of the Mollusca, appeared during 1925 and 1926. About 6,500 pages of the work have now been issued. The editor and publishers are to be congratulated on the output of more than 1,100 pages during 1931, and on maintaining the high standard of authorship and production referred to in our previous notices.

(1) In this part Prof. Fuhrmann completes his account of the Cestoda, characterised by concise and skilful treatment and by its excellent illustrations, seventy of which in the present part are original. The author does not favour the view that the pseudophyllid Cestoda, for example, *Caryophyllæus*, are nearly related to the Trematoda; he regards as much more probable that the Trematoda and Cestoda are quite separate and have been derived from nearly related Turbellaria, for example, the Rhabdocœla, and that resemblances between the Pseudophyllidea and the Trematoda are due to convergence.

(2) A short general introduction to the Annelida by Dr. Riesiger leads to Prof. Hempelmann's account of the structure, reproduction and biology of the Archiannelida and the Polychæta. While this is for the most part altogether adequate, a fuller account of the histology of the nervous system would have been welcome and would have afforded the opportunity for a useful summary of the extensive work on the neurones and their fundamental inter-relationships in Polychæta and other Annelida.

(3) In Prof. Baltzer's hands the Priapulida (14 pp.), Sipunculida (47 pp.) and Echiurida (100 pp., unfinished) receive thorough treatment. The author inclines to the relationship of the Priapulida to the Kinorhyncha, and holds that the Sipunculida and Echiurida are separate and that the old group of Gephyrea must be definitely abandoned. New details are given on the structure of the uterus of *Bonellia*. This uterus is divided into two parts—one for the eggs and the other harbouring the dwarf males—separated by a narrow canal closed by a plug of mucous which is dissolved at the time of egg-laying when the eggs pass into the second chamber and are there fertilised on their way to the exterior. Dr. Baltzer provides a useful summary of the observations and experiments on the determination of sex in the post-larval development of *Bonellia* and on the production of various grades of intersexes. He directs attention, in his

account of the trochosphere of *Echiurus*, to the mesoderm which, as he showed in 1917, does not develop from teloblasts and does not become segmented ; in both these points he corrects the well-known account by Hatschek which is repeated in most textbooks. From the list of parasites of the Echiurida is omitted *Oligognathus bonelliæ*, parasitic in the cœlomic cavity of *Bonellia.*

(4) Lief. 1 contains Dr. Herman Graf Vitzthum's account of the Acari, in which a fair share of attention is devoted to the internal anatomy and to the section on ecology. While the Acari are probably monophyletic, the author points out that the common stem must have divided, possibly in early Devonian times, for the mite *Protacarus crani* from the Old Red Sandstone, Aberdeenshire, described by Hirst, already shows some differentiation towards the recent Eupodidæ. At present there are six main branches forming the recognised sub-orders. The number of genera of Acari approaches 1,000 and of the species about 6,000.

Lief. 2 consists of accounts of Rhabdopleura by Drs. B. Bergersen and Hj. Broch and of *Balanoglossus* by Prof. van der Horst, both well done and fully illustrated. In the first part the authors examine the view put forward by Schepotieff that the Graptolites were Pterobranchia, which they conclude is untenable.

The account of the Merostomata (32 pp. unfinished) by Prof. U. Gerhardt and of the Pycnogonida (64 pp.) by Dr. H. Helfer constitute the third section. In the latter, the development, larval stages, ecology and phylogeny are the most interesting sections.

(5) These two parts form the first portion of the account of the Amphibia by Dr. Franz Werner. A brief survey of the main facts of structure, development, distribution and biology of the class precedes the detailed consideration of the osteological features and the classification of the Stegocephali and the excellent account, with many good figures, of the Apoda (Gymnophiona).

(6) This contains the first instalment of Dr. O. V. Wettstein's description of Sphenodon—the skeleton and teeth (42 pp.), musculature (53 pp.), and nervous system (unfinished 23 pp.), all of which are described in considerable detail and are well illustrated. The labelled drawings of the posterior, ventral, dorsal and lateral aspects of the skull will be helpful to advanced students for such drawings are not readily accessible elsewhere, and a word of commendation is due also for the account of the epiphysis and the pineal eye.

(7) Dr. Stresemann continues his admirable account of the birds and discusses in particular the various movements of the wings and the different types of flight in relation to the anatomy of the bones and muscles and to the feather-planes. Due attention is given to the swimming and diving of birds and the movements in relation thereto of wings, feet and tail. An interesting description follows of the structures concerned in the production of voice and song, in the alteration of tone and in resonance. In the section on geographical distribution are found data on the rate of spread of species and on discontinuous distribution as a result of the past history of the earth.

Short Reviews

Grundzüge der regionalen Limnologie. Von Prof. Dr. Einar Naumann. (Die Binnengewässer: Einzeldarstellungen aus der Limnologie und ihren Nachbargebieten, herausgegeben von Prof. Dr. August Thienemann, Band 11.) Pp. xiv+176+8 Tafeln. (Stuttgart: E. Schweizerbart'sche Verlagsbuchhandlung (Erwin Nägele) G.m.b.H., 1932.) 20.50 gold marks.

DR. EINAR NAUMANN, professor of limnology at the University of Lund and director of the Limnological Laboratory at Aneboda, Sweden, gives us an instructive discussion on modern principles of research relating to the study of fresh-water lakes. Among his many works on limnology he has already contributed two volumes to "Die Binnengewässer" on the foundations of experimental plankton investigation and an introduction to the study of lake bottoms. Closely related to these is the present work on regional limnology, which embraces a large number of side issues concerned with the detailed investigation of fresh water lakes, their origin, form and contents, both organic and inorganic, involving the co-operation of geologist, physicist, chemist and biologist. This is a very new branch of biological science although a large amount of preliminary work has already been accomplished, especially at Prof. Naumann's own laboratory, which is the headquarters of all such research.

First and foremost in the work are concerned the life in the lakes with the available food and the mapping of the regions and classification with regard to all factors involved—the nature of the bottom, chemical contents, physical features and the plant and animal life present. By such maps one can tell at a glance the kind of lake and its probable inhabitants. The lakes are classified according to the amount and quality of food they can produce and these again are sub-divided. A regular order of these waters is now established so that one can foretell to a large extent what kind of plants and animals inhabit any lake. An enormous amount of work still remains to be done and this is an important addition to the literature of the subject.

Partridge Disease and its Causes, including the Report and Suggestions of the Country Life *Committee of Enquiry into the Diseases of Partridges during the Season 1931–1932.* Edited by Major M. Portal and Dr. Walter E. Collinge. Pp. ix+96+7 plates. (London: *Country Life*, Ltd., 1932.) 12*s*. 6*d*. net.

THE prevalence of a new or hitherto unrecognised disease amongst partridges, which caused heavy mortality during the earlier winter months of 1931, brought about the formation of a *Country Life* committee of inquiry, under the chairmanship of Major M. Portal and with the assistance of Dr. W. E. Collinge as pathologist. While partridges are subject to several fatal diseases, the special features of this epidemic were loss of weight, reluctance of the bird to feed, congestion of the cæca, stomach invariably empty; and the cause was found to be a nematode parasite, *Trichostrongylus tenuis*, harbouring in thousands in the cæca. The life-history of the strongyle has been worked out: it has been found to be spread with the fæces, from which the larvæ swarm up blades of vegetation, with which they are engulfed by other partridges. Although no wild bird seems to be concerned in the distribution of the parasite, earthworms are very frequent carriers of both eggs and larvæ. Any factor which weakens the resistance of partridges predisposes to fatal attack, and amongst such factors the Committee suspects interbreeding, overcrowding in winter, insufficient food, and unfavourable weather conditions. Some of these may be associated, as several replies to a questionnaire issued by the Committee suggest, with modern conditions of farming and roads. Special chapters have been written by experts upon methods of feeding and breeding, so that there has been gathered together in this volume a body of observations and information which no owner of partridge land can afford to ignore.

Rhenium (Opyt monografii elementa No. 75). By E. S. Kronman. Pp. 85. (Moscow and Leningrad: N. K. T. P. The Gold and Platinum Institute, 1932.) 1r. 25k.

MENDELEEFF'S dwi-manganese was discovered in 1925 and the name rhenium assigned to it by W. and I. Noddack has become accepted. Since its discovery, rhenium has been the subject of more than a hundred scientific communications and Dr. Kronman's Russian monograph follows closely upon Mr. P. M. Tyler's "Rhenium (and Masurium)" issued as an information circular by the U.S. Bureau of Mines and Dr. W. Schröter's "Das Rhenium", both of which appeared about two years ago.

This latest work is the most comprehensive, including as it does as complete an account of the geochemistry, isolation, chemistry and physics of the new element as the author has been able to ascertain from the publications accessible to him. He has been somewhat dependent upon abstracts in the *Chemisches Zentrallblatt* for the non-German contributions to the subject (including the letters in NATURE during 1925 *et seq.*). He has, nevertheless, omitted very little of importance and it is therefore regrettable that this monograph, being in Russian, is inaccessible to all but a few chemists and others who are interested in the new element.

J. G. F. DRUCE.

Architectural Graphic Standards: for Architects, Engineers, Decorators, Builders and Draftsmen. By Charles George Ramsey and Harold Reeve Sleeper. Pp. ix+233. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1932.) 37*s*. 6*d*. net.

IN recalling the important buildings upon which architects and their assistants worked in bygone years, it does not seem as if the elaborate 'simplicity', claimed for this book, is required. Specifications and details were prepared in those days with an assurance and success, which no mere "graphic and diagrammatic assembly of data, standards and information" would have produced. If this book may be regarded as supplying between two covers a large amount of valuable information for students, it is well, though greater simplicity might be desired. It may be seriously doubted whether any practising architect in Great Britain would be troubled with this, or any similar, work. It would not be proper to criticise American building methods unfavourably because they differ from English methods; suffice it to note, that the authors have shown their knowledge and have exercised their skill and ungrudging labour in the preparation of the book. P. L. M.

Kamet Conquered. By F. S. Smythe. Pp. xvi+420+48 plates. (London: Victor Gollancz, Ltd., 1932.) 16*s*. net.

SEVERAL attempts had been made on Kamet before Mr. Smythe's successful expedition of 1931; so long ago as 1912 Mr. C. F. Meade discovered the best line of approach from the east by which he reached the mountain in the following year and gained an altitude of 23,500 ft., or less than two thousand feet short of the summit. Mr. Smythe's party used the same route by the East Kamet Glacier and Meade's col, reaching the top, 25,447 ft., with some difficulty but without accident. This volume, however, is more than a mere record of this and other climbs in the Himalayas. It contains a discussion of many of the problems of mountaineering, material, physiological and psychological. These reflections from an experienced climber are of great value and make the book of real use to future expeditions.

Identification of Vitamin C*

By PROF. A. SZENT-GYÖRGYI, Director of the Institute of Medical Chemistry, University Szeged

ABOUT a year ago vitamin C seemed to be the most elusive of vitamins, apparently defying all attempts at isolation and identification. To-day this substance can be bought at a relatively low price, neatly sealed in tubes, in the form of beautiful white crystals. It is even used as a reagent for reducing gold and silver in microscopical technique. Also its chemical constitution is cleared up to a great extent.

In spite of this, however, the development of our knowledge has not been so dramatic, and these results have been the outcome of laborious work extending over more than ten years. This vitamin was crystallised more than five years ago and was, so far as we know now, the first vitamin ever isolated in the crystalline form.

The development in our knowledge of vitamin C has taken place in four distinct steps. The first step was the observation of 'hexuronic acid' in 1927 and its subsequent isolation and partial identification at Cambridge in 1928. This observation and isolation in itself was the result of many years extensive studies on oxidation systems of plants and animals. I was led to these studies by the belief that the adrenal gland was in some way involved in oxidation processes. Before this function of the gland could be understood, more had to be known about oxidation itself. Thus oxidation systems were examined one by one, until a new oxidation system was brought to light in which the central rôle seemed to be played by an interesting substance with very striking chemical properties. This substance has been isolated and found to be a monocarboxy acid corresponding to the formula $C_6H_8O_6$. This formula, together with some qualitative reactions, suggested a relation with the hexuronic acid series. The substance was thus called 'hexuronic acid' and the oxidation system the 'hexoxidase system'. More recent results, however, obtained in Prof. Karrer's and Prof. Haworth's laboratories, do not bear out this relation to uronic acids and, I have proposed, in association with Prof. Haworth, to call it henceforth 'ascorbic acid'.

The most remarkable chemical property of this acid is its very high reducing power, unique among purely carbon compounds. This reducing power is the more remarkable, since the oxidation of the acid itself is reversible. It is in fact this reversible oxidisability by which the substance exerts its biological activity. It is oxidised and reduced alternately, giving off and taking up two atoms of hydrogen, thus acting as a hydrogen carrier between different parts of its oxidation system.

This same substance has been found in relatively large quantities in the adrenal cortex, of which it forms definitely a specific constituent.

The second step to the establishment of the chemical nature of vitamin C was the discovery of the antiscorbutic properties of ascorbic acid. The striking similarity in chemical properties and distribution of the acid and the vitamin has been evident since the discovery of the former. It was not, however, until the autumn of 1931 that, in collaboration with J. L. Svirbely at the Institute of Medical Chemistry at the University Szeged, I was able to find the necessary external condition for the test of the antiscorbutic activity.

Meanwhile evidence was accumulating that one of the reducing substances of plant juice and the vitamin were identical. Tillmans in Germany pointed out in his extensive studies the very close parallelism of both, not only in distribution, but also under different experimental conditions. In the end he arrived at the conclusion that the main reducing factor and the vitamin were identical. In the United States, C. G. King and his collaborators emphasised the reducing power and acidic nature of active fractions, while S. S. Zilva in England has also found many close parallelisms between reduction and antiscorbutic activity. This author, however, also found differences which have led him to believe that these factors are not identical.

Our first test, undertaken by J. L. Svirbely in the autumn of 1931, clearly brought out the antiscorbutic activity of 'ascorbic acid'. We were able to show, that not only had this acid a strong antiscorbutic activity, but also that the antiscorbutic activity of lemon juice corresponded to the activity of the quantity of ascorbic acid which it contained. Our results were not announced until March 1932, by which time the experiments were repeated three times with identical results.

At this time, March 1932, W. A. Waugh and C. G. King obtained crystals from lemon juice, which they thought to be identical with hexuronic acid and which seemed to have some action on the vitality of animals. Two months later the same authors were also able to present evidence for this identity and the antiscorbutic activity.

Our own experiments were checked at our request by S. S. Zilva and L. J. Harris and were confirmed. This evidence may be summarised by saying that all the preparations of ascorbic acid tested had strong antiscorbutic activity. The investigation had now arrived at a most difficult point. The question arose, whether the activity of the preparations was due to the ascorbic acid itself or to a contamination of the preparations with some more potent substance. The daily protective dose of ascorbic acid is 0·5–1·0 mgm. Should the crystals have contained 0·1 per cent of a substance, acting (as other vitamins) in doses of 1γ, their activity could be explained by this contamination. Our own substance employed in the test as well as the preparations of Waugh and King had a melting point 10° lower than that of pure ascorbic acid, and thus certainly contained more than 0·1 per cent impurity. This question, whether the activity is due to a definite substance or to contaminations, applies to all research on vitamins and is usually one of the most difficult problems to solve.

---

*Substance of a lecture given at the University Club, Szeged, on December 15.

There is, however, much circumstantial evidence in favour of the identity of vitamin C and ascorbic acid. The parallelism in distribution and behaviour under experimental conditions, and the quantitative correspondence of the antiscorbutic activity of plant juice and its ascorbic acid content, point in this direction. Harris has shown that this quantitative correspondence holds also for the adrenal cortex with its high ascorbic acid content. Svirbely has shown that the ascorbic acid disappears from the gland very readily on vitamin-free diet, thus demonstrating the inability of the animal to build up this substance. Svirbely has also shown that our ascorbic acid, prepared from the adrenal gland, retained its antiscorbutic activity after five recrystallisations. Work on purely chemical lines alone could give direct and definite evidence of the identity of the vitamin and ascorbic acid. Unfortunately, the great scarcity of the material rendered such work impossible. Fresh adrenal glands, a convenient source for preparations, were not available in the necessary quantity, and all our efforts to prepare ascorbic acid from lemons, oranges, tomatoes, or cabbages on a large scale have failed.

In the third step in our work these difficulties were overcome and the way opened for direct chemical work, providing definite evidence for the identity of vitamin C and ascorbic acid. This progress we owe to the discovery that local varieties of Hungarian red pepper (*Capsicum annuum*) contain the acid not only in relatively large quantities but also under conditions which make its isolation exceedingly simple. It is due to this fact that during the last few months Svirbely and I have been able to prepare a full pound of crystalline ascorbic acid for chemical studies. Unhampered thus by the lack of material, we could set out with L. v. Vargha to study derivatives of ascorbic acid, an investigation which has led to the preparation of a mono-acetone derivative. This substance seemed to be almost ideally suited for our purpose. It forms big, beautiful crystals with great ease and is stable in anhydrous solution, from which it can be recrystallised without difficulty. After due recrystallisation the original acid can be recovered unchanged by simply boiling it in water for a few minutes. Since the acetone derivative does not hydrolyse in cold water immediately, it was found in the antiscorbutic experiment to be but moderately active. The ascorbic acid, recovered from the recrystallised derivative, was fully active, a definite evidence for the identity of ascorbic acid and the vitamin.

The last and perhaps the most difficult step towards the definite chemical identification of the vitamin is the establishment of the chemical constitution of ascorbic acid. The possibility of preparing ascorbic acid in quantity has also opened the way for the chemical analysis. It was a great privilege for my American collaborator Svirbely and myself to be allowed to supply material to Prof. Haworth at Birmingham and Prof. Karrer at Zurich for this analysis.

The work of the laboratories at Zurich and Birmingham has clearly brought out that ascorbic acid is, confirming my original findings, a simple substance, consisting of 6 carbon, 8 hydrogen and 6 oxygen atoms; it contains one carboxy group, but is, however, not a member of the uronic acid series, and thus is not a hexuronic acid. Two of the carbon atoms are present as $C = O$ groups forming a keto or aldehyde group with strong enolisation. One carbon is present as CH_2. The remaining two carbon and oxygen atoms are present as alcoholic groups. In this way the essential features of the molecule are cleared up and there remains only to ascertain the relative position of these groups.

It is hoped that the fact that the vitamin is a specific constituent of the adrenal cortex, from which it disappears on vitamin-free diet, will open up many fascinating problems to research and may contribute to the deeper understanding of the relation of hormones and vitamins.

There is one aspect of these investigations on which I look with pride and gratitude. This work has been made possible only by the closest international collaboration. It has been helped by Dutch, English and American hospitality and generosity. At present it is aided by the Josiah Macy, Jr. Foundation.

Geology in the Life of a Nation

THE Indian Science Congress held its twentieth annual meeting this year at Patna under the presidency of Dr. L. L. Fermor, Director of the Geological Survey of India. In his presidential address Dr. Fermor refers to some matters of general interest in the history of the Indian Science Congress, which is modelled on the lines of the British Association, and, like that body, meets annually at different towns.

The initial meeting that led to the formation of the Congress was held in 1912 in the rooms of the Asiatic Society of Bengal and that Society has since taken the general responsibility for the organisation of the Congress year after year. Until 1931 the Congress had no permanent organisation, but a constitution was then adopted whereby it did become a continuous organisation under the title of the Indian Science Congress Association with a roll of permanent members—though the close association with the Asiatic Society of Bengal is to be maintained. Dr. Fermor appeals to generous donors to remember the Indian Science Congress now that it has an independent existence, since it is hoped that in the future it may have funds for financing special items of research.

Special mention is made of the new periodical *Current Science*, the first issue of which as a monthly journal appeared in July 1932. This periodical has been modelled on the lines of NATURE and there has been no lack of material suitable for publication, but the financial position of the new venture at present leaves much to be desired, though this all-India journal of science can be self-supporting with a minimum of five hundred subscribers.

It is certainly very clear that the Indian Science Congress has fulfilled a want. At the first meeting there were 79 members, a presidential address was given, and 35 papers were read, and the published proceedings occupied eight pages of print. At the nineteenth meeting in 1931 the number of full and associate members was 690 and of student members 183. There were ten presidential addresses, general and sectional, and 693 papers were communicated occupying 467 pages of *Proceedings*.

In choosing as the subject for his presidential address, "The Place of Geology in the Life of a Nation", Dr. Fermor has left the sting of his remarks to the tail. All the countries of Europe, excluding Russia, Finland, Scandinavia, Poland, Greece and Turkey can be fitted into the area of India excluding Burma. The Geological Surveys of the various European countries have staffs numbering more than 250, of which 78 are employed in Germany and 52 in Great Britain. Yet for the adequate geological survey of a corresponding area, the staff of the Geological Survey of India has just been cut down in a most drastic way. It now has only 24 officers, 6 of whom are employed in Burma, leaving only 18 for the whole of the vast area of India. It is small wonder, therefore, that the Director of the Geological Survey should seek to analyse the position which geology should occupy in the life of a nation. In so doing he interprets geology as geographical evolution and states that "geography is the branch of geology that describes the particular shape and form of the earth's surface at the present time".

Although there are few geographers who would accept this definition, they would heartily agree with Dr. Fermor upon the necessity for a detailed study of that portion of the human environment which comes within the domain of the geologist. The position of the capital of India has been dictated by the physical structure of the subcontinent, which in turn depends on its geology. Similarly, the position of the commercial capital, Calcutta, dependent as it is on the nature and extent of its hinterland, has been similarly determined. The black earth region that forms the natural hinterland of Bombay and provides the Bombay cotton mills with their huge supplies of raw cotton, depends in turn upon the existence there of the black soil derived in the main from the Deccan lavas. The close correspondence between the political map of Europe and the orographical and geological is emphasised and it is in particular pointed out how the less stable political units of Europe are those which are less clearly natural geographical or geological units. "India is fortunate, however, in that the general geological conditions have caused the inhabitants, in spite of their diversity of race, religion and language, to be welded after struggles through the ages into one political unit. As the national boundaries in central Europe, the boundaries between the provinces in India pay little attention in many cases to geological considerations. The province of Bihar and Orissa, for instance, . . . is an excellent example of the violation of natural principles by provincial boundaries. But as long as the central political control remains, it does not matter seriously that the boundaries of our provinces take such little account of natural factors. Were the central control, however, removed and all political relationship to one general suzerain power severed, then the future history of India would again become as confused as it was in the past and as confused as that of Central Europe has been throughout the ages and promises to become again in the future."

This is truly the geographer's point of view and it is interesting to find it so clearly voiced by a geologist. There is an unhappy note when Dr. Fermor says towards the end of his address that "at present the scope for new employment for geologists in India has fallen almost to zero". He urges, however, the continued need for geological classes in university institutions as a "branch of general culture".

One cannot regret feeling that Dr. Fermor has not been able, because of his official position as director, to add point to his arguments by reciting some, at least, of the great work which has been carried out by the Geological Survey of which he is head. So it is to be feared that the reduction of this essential service in such an amazingly drastic fashion has passed without the notice that it should have attracted from men of science. For the Survey has a great and continuous record of work and it is to be hoped that under Dr. Fermor's guidance it will force an adequate recognition of its services to the country.

This is not the place for reciting what the Survey has done, but perhaps its Director may be able to remove what have in the past been two of the major criticisms: (1) the perhaps rather inadequate means of publication of the detailed mapping carried out by the officers, whose work in this respect remains unknown even to geologists in India itself, while there is apparently nowhere in Britain where the one-inch maps, on the preparation of which a large proportion of the officers' time is expended, can ever be consulted; (2) the serious time lag between field-work and publication, especially important where problems of economic geology are being investigated.

L. DUDLEY STAMP.

Tercentenary of Samuel Pepys

By T. E. James

THE three hundredth anniversary of the birth of Samuel Pepys, a moving, dramatic figure in the political and social annals of the Restoration period, falls on February 23. Born either at Brampton, near Huntingdon, or in London (so records say), he was educated at St. Paul's and Magdalene College, Cambridge, graduating there in 1660. In 1655, Pepys married and had, for some time, to face comparative poverty. He was favoured, however, with the patronage of Sir Edward Montagu, and was employed as secretary to the expedition for bringing Charles II from Holland; this leading to permanent and official employment at the Admiralty. In 1679 Pepys was committed to the Tower on a State charge, but was incontinently released.

Pepys's "Diary" was begun on January 1, 1659-60. It was written in great secrecy. The final entry was made on May 31, 1669. The "Diary" itself was not published until 1825. Therein, the high intent, the ignoble, and the frailties of Pepys's own life resolve into an inexplicable, baffling display of inwardness.

Not the least monument to Pepys, where memory is deep and lasting, was the bequest of his library and MSS. collections (by preference) to Magdalene College, Cambridge. An excellent general account of the Pepysian Library has been given by H. B. Wheatley (1880).

During the early part of Charles II's reign, the Royal Mathematical School of Christ's Hospital, still part of the major foundation, was established. Pepys, as a governor, took a lively interest in its efficient administration. On February 15, 1661-2, Pepys was made a younger brother of the Trinity House and in 1676, Master of the Trinity House. He was elected Master of the Clothworkers' Company in 1677.

Readers of NATURE will be more particularly interested in the association of Samuel Pepys with the Royal Society of London in its early days, particularly with those men who had been most active in its institution. In course of time we witness Pepys's own inclusion in the organisation; ultimately, his assumption of the office of president.

We need entertain no doubt that Pepys was cognisant of the various steps that were taken to establish the Society. He had friends of quality, who would relate what had happened, whilst Pepys himself, Clerk of the Acts (Navy), was favoured in the Restoration Court circle, where news spread apace. Hence, on January 9, 1664-5, Pepys is able to record that the Royal Society's charter book had been brought to Whitehall, and that the founder's signature and that of the Duke of York were duly inscribed. Indeed, he had not long to wait for acceptance amongst the philosophers. On February 8, 1664-5, "Samuel Pepys, Esq., was proposed candidate by Mr. Povey", the business prior to this being the election of Edward, Earl of Clarendon, the famous Lord Chancellor. Mr. Pepys found himself in excellent company. Thomas Povey, it may be mentioned, was an original fellow. He had mechanical gifts and for many years proved serviceable to the Society. Evelyn considered him to be "a nice contriver of all elegancies".

On February 15, 1664-5, Pepys was duly elected, signing the charter roll then and there. Going home, Pepys recorded his experience thus:—

> "With Creed to Gresham College, where I had been by Mr. Povy; and the last week proposed to be admitted a Member, and was this day admitted, by signing a book and being taken by the hand by the President . . . and some words of admittance said to me. But it is a most acceptable thing to hear their discourse, and see their experiments. After this being done they to the Crowne Taverne, behind the 'Change, and there my Lord and most of the company to a club supper; . . . Above all, Mr. Boyle to-day was at the meeting, and above him Mr. Hooke, who is the most, and promises the least, of any man in the world that ever I saw."

Pepys chronicles, as also amongst the company, Sir Paul Neile, Sir Robert Moray, Dr. Clarke, Dr. Whistler, and Dr. Goddard. On March 1, following, the subjoined entry occurs:—

> "At noon I to dinner at Trinity House[*], and thence to Gresham College, where Mr. Hooke read a second very curious lecture about the late Comett[†]; among other things proving very probably that this is the very same Comett that appeared before in the year 1618, and that in such a time probably it will appear again, which is a very new opinion. . . . Then to the meeting. . . ."

In the following week (March 8), Pepys goes to the weekly meeting as a fellow. A letter was read from Huyghens to Sir R. Moray, containing first his desire to be more particularly informed about the pendulum watches committed to Major [later Sir Robert] Holmes. Mention was thereupon made of Holmes's relation of the performances of pendulum watches on his voyage to Guinea, and doubts were cast. Accordingly, Mr. Pepys was asked to inquire into the matter for the satisfaction of the Society. On March 15, Pepys gave an account of information that he had obtained from the master of the Jersey ship who had sailed with Holmes on the Guinea voyage. Something additional devolved on Pepys. He was desired to bespeak a man at Deptford for diving. The diver was to be sent to Robert Hooke to be instructed by him concerning the use of "air-boxes" under water. Later, in May, Lord Brouncker reminded

---

[*] The Navy Office, where Pepys resided, lay between Crutched Friars and Seething Lane, by the Tower.

[†] See in this connexion, NATURE, Feb. 7, 1884, p. 345, article in "Our Astronomical Column".

Pepys of this commission, as the season was favourable. On March 22, the subject of Holmes's watches arose, and Pepys was requested to procure the journals of those masters of ships who had been with Holmes in Guinea and differed from him.

The incidence of the Plague and the Great Fire which followed were periods of intensive public anxiety and apprehension, and we lose contact with the College world for some time. But on November 14, 1666, Pepys records that Dr. Croone had told him that at that night's meeting, "which, it seems, they now have every Wednesday again", there were experiments on blood transfusion. A year later (November 21, 1667), there is another reference :—

> . . . "I to the office, where did much business till after candlelight, and then my eyes beginning to fail me, I out and took coach to Arundell House, where the meeting of Gresham College was broke up ; but there meeting Creed, I with him to the taverne in St. Clement's Churchyard."

On November 30, 1667, Pepys tells us that he went to Arundel House to the election of officers of the Royal Society for the next year ; that he was near being chosen, but glad that he was not, for he could not have attended, but took it as a mighty respect to have been named. Also, that the company was great, the elections long.

On April 2, 1668, Pepys mentions a visit to the Royal Society, with Lord Brouncker, and of being "forced to subscribe" to the building of a College ; and that he "did give forty pounds". Pepys held views adverse to the scheme, and these may have reflected themselves in a partial withdrawal of interest, for not until November 30, 1674, do we again pick up the threads of association with the Society. But it is with enhanced prestige. At the anniversary meeting, Mr. Pepys is among ten new members chosen for the council. His ally, Sir Joseph Williamson (P.R.S., 1677), was also of the number. Pepys attended the meeting on December 3, when a resolution was taken that every member of council should provide an experimental discourse for the Society, to be made within the year, either by himself or by some other member of the Society ; *or*, "to pay forty shillings". Pepys promised a discourse.

On December 17, Pepys is placed upon a committee to consider how Dr. Wilkins's legacy of £400 might be laid out. Also, he was joined with Sir R. Southwell and the president in an application to Prince Rupert "concerning the mischief which his glass-house does to Chelsea College". In January ensuing the president announced his discourse. Mr. Pepys, he said, had offered to make his the next week after his own ; it does not appear, however, that Pepys held to his offer.

On February 18, 1674–5, "Mr. Isaac Newton" was admitted a fellow. Since Pepys was a member of council, there is a presumption that he was present on this particular occasion. Pepys was irregular in his attendances, however, during the year, and he was not continued on the council. But his light was only temporarily dimmed, for on November 30, 1676, he re-appears as one of ten new members, and among these were Sir Christopher Wren and John Evelyn. Again Pepys served twelve months.

In the politically stormy year of 1680, "far away at Newmarket, Pepys was taking down, at the dictation of his sovereign, the tale of that miraculous escape from Worcester of twenty-nine autumns before" (Bryant).

We now pass to the year 1681, when Pepys re-appears in the Royal Society. At the anniversary meeting on November 30, he enters the council, and with him, Evelyn and Flamsteed ; Sir Christopher Wren is president. Hooke was a colleague. Pepys served for one year. Coming to 1684, at the anniversary meeting on December 1 (St. Andrew's Day falling on a Sunday), Sir John Hoskyns in the chair, Samuel Pepys, chosen for the council, is also elected president of the Society. Notwithstanding that his attendances were infrequent, he was, in 1685, continued in the presidency for yet another year, this nomination marking the closing and final period in that office.

Here it may be mentioned that at a council on June 2, 1686, the first book of Newton's "Principia" was ordered to be printed. Pepys was not present, nor on June 30, when it was ordered that the president be desired to license the book. Sir John Hoskyns occupied the chair. Pepys's imprimatur was given on July 5.

Samuel Pepys was never a very healthy man, and he died at Clapham on May 26, 1703. He was buried in St. Olave's Church, Crutched Friars. His portrait, by Kneller, and his own gift, adorns the apartments of the Royal Society.

Obituary

PROF. HARLAN W. FISK

THE science of terrestrial magnetism has lost an outstanding investigator and the staff of the Carnegie Institution of Washington an esteemed member by the sudden death, on December 26, of Prof. Harlan Wilbur Fisk, chief of the Section of Land Magnetic Survey of the Institution's Department of Terrestrial Magnetism. During his long period of service with that organisation, extending over more than a quarter-century, he contributed much to the success of the world magnetic survey both by personal participation in the observational work and by planning and supervising the work at repeat-stations for obtaining data where most needed for investigations in his complex field.

Prof. Fisk was born at Geneva, Kansas, on September 25, 1869, but his youth was spent in Minnesota where he received his fundamental scientific training at Carleton College, Northfield. Here his enthusiasm for mathematics and astronomy was awakened by contact with such inspiring teachers as W. W. Payne and H. C. Wilson. In 1899 he was appointed professor of mathematics at Fargo College (North Dakota). It was here that the problem of terrestrial magnetism first engaged his attention and he devoted his summer vacations (1904–6) to magnetic observations for the United States Coast and Geodetic Survey in the north-central and western States. His interest in this field grew so rapidly that in October 1906 he adopted it as his life work when he became associated with the Department of Terrestrial Magnetism.

Here Prof. Fisk focused his activities on the land magnetic survey—one of the major undertakings of the Department. He made two detailed surveys of the Bermuda Islands, in 1907 and 1922, and in 1908 conducted magnetic expeditions in Central America, in the West Indies, and in the northern countries of South America. He was also greatly interested in the investigations of possible eclipse effects on the earth's magnetic field and participated in several eclipse expeditions of the Department—the last was on the occasion of the eclipse of August 21, 1932, when he was in charge of three observing parties in New England. He took a prominent place in the instruction of many of the Department's most active observers and in the laborious observations during many years in Washington, D.C., relating to the control of instrumental outfits and the determination of the provisional international magnetic standards.

Prof. Fisk's chief research contribution was the investigation of secular changes in the earth's magnetism and of the shifting of isoporic foci disclosed by magnetic data obtained at strategic repeat-stations by observers under his supervision. Mature deliberation led him to infer that secular changes in the earth's magnetism determined by observations on its surface might reflect changes within the earth's crust or interior. At the time of his death, he had in preparation an exhaustive paper on this subject.

Besides membership of a number of scientific societies, Prof. Fisk was an active worker in the American Geophysical Union, being secretary of its Section of Terrestrial Magnetism and Electricity in 1929–32. Because of an unusual breadth of culture extending far beyond the confines of his scientific activity, it was his pleasure and privilege to render important service to his community in its civic and religious life. His quiet disposition, generous nature, and helpful counsel, won him the esteem of his colleagues and friends. Those who shared his acquaintance and work, will mourn with his widow and four children his premature passing.

H. D. HARRADON.

MR. B. H. SOULSBY

MR. B. H. SOULSBY, who died at Reading on January 14, aged sixty-eight, was for nearly thirty-eight years in the service of the Trustees of the British Museum, first at Bloomsbury and later at South Kensington. He was educated at Cheltenham College and at Corpus Christi College, Oxford, and also studied at Göttingen. He entered the service of the Trustees as a second-class assistant in the Department of Printed Books in 1892, and became successively superintendent of the Map Room, of the Copyright Office, and finally deputy superintendent of the Reading Room. During his time at Bloomsbury, he catalogued the library of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England, and translated some early geographical works. In 1902 he published a small pamphlet on the earliest two maps which bear the name America.

In 1909 Mr. Soulsby was transferred to the Natural History Museum as assistant in the Director's office, and in January 1921 he was appointed librarian in succession to the late Mr. B. B. Woodward. His principal official duty was to continue Woodward's Catalogue of the Natural History Library, a monument of bibliographical care and research and a mine of information, the value of which was recognised far beyond the limits of the Library to which the work refers. Woodward had compiled six volumes and one supplementary volume, and at the time of Mr. Soulsby's retirement, the second supplementary volume was well on the way to completion.

At the time of his death, Mr. Soulsby was seeing through the press the final stages of a revised, second edition of the "Catalogue of the Works of Linnæus . . . in the British Museum". The first edition, which was compiled by B. B. Woodward and W. R. Wilson, was a quarto publication of 27 pages, comprising some 580 entries. The second edition will contain about 300 pages of text, with nearly four thousand entries, accompanied by bibliographical notes, plates and an index.

It was upon this index that Mr. Soulsby was engaged, with his accustomed industry and enthusiasm, at the time of his death. The forthcoming publication of this Linnæan Catalogue is a matter of great interest to librarians in Sweden, from several of whom Mr. Soulsby obtained considerable assistance in its preparation. The compiler used to claim that the collection of Linnæana at South Kensington was second only in richness and importance to that at the Royal University Library of Uppsala, and if this is so, it is largely due to Mr. Soulsby's great generosity, inasmuch as ever since he undertook the work of producing a second edition of this catalogue, he was continually presenting rare and costly Linnæana to the library at South Kensington.

MR. J. L. S. HATTON

JOHN LEIGH SMEATHMAN HATTON, who died on January 13, aged sixty-seven years, was the first principal of East London College and, at the time of his death, Vice-Chancellor of the University of London. He was born at Street Aston on May 27, 1865, the son of the Rev. J. L. S. Hatton, rector of West Barkwith, Lincolnshire. He died at his home at Sanderstead, Surrey, and is survived by his widow and two sons.

Mr. Hatton entered Oxford with a scholarship at Hertford College and obtained a first class in the school of mathematics in 1889 and a second class in natural science (physics) in 1890. He acted for a short time as demonstrator in the Clarendon Laboratory and was called to the Bar by Lincoln's Inn.

In 1892, Mr. Hatton began to organise the day and evening teaching work of the People's Palace in Mile End Road, and by his unremitting effort and enthusiasm, supported by the interest and encouragement of the Drapers' Company, he built up an institution which, in 1907, became East London College, a school of the University of London, with day courses leading to degrees of the University in the faculties of arts, science and engineering. Mr. Hatton became a member of the Senate of the University in 1903, representing the faculty of science, and continued in this office until on the reconstitution of the University, he became a member *ex officio*.

Mr. Hatton's work for the University was as thorough and valuable as that for his own College. He was dean of the faculty of science from 1922 until 1926, chairman of the Board of Studies in Mathematics for many years, was elected deputy Vice-Chancellor in 1930, and assumed the office of Vice-Chancellor last September. He was for many years head of the Mathematical Department at East London College, and was appointed University reader in geometry in 1927 on his retirement from this post. He was the author of several mathematical works, including "The Theory of the Imaginary in Geometry", but his main interests were in teaching and administration.

MR. WILLIAM H. V. WICKES of Bristol died on February 2, aged eighty-six years. Wickes was a well-known local geologist and had been guide, philosopher and friend to many of the older school, British and foreign. He wrote short papers on the Rhætic bone-bed and the mineral beekite and made a varied collection, passing his best things on to the British and the Bristol Museums.

WE regret to announce the following deaths:

Prof. Johan van Baren, professor of geology and mineralogy in the Agricultural University of Wageningen, Holland, an authority on soil mineralogy, on February 7, aged fifty-seven years.

Lieut.-Col. J. C. G. Kunhardt, formerly of the Indian Medical Service, who did valuable work on plague prevention in India, and also in the advancement of the rubber industry, aged fifty-seven years.

Prof. A. G. Leonard, professor of geology in the University of North Dakota and State geologist, on December 17, aged seventy-seven years.

Sir Daniel Morris, K.C.M.G., assistant director of the Royal Botanic Gardens, Kew, in 1886–98, and president of Section K (Botany) of the British Association in 1919, aged eighty-nine years.

Prof. Ormond Stone, director of the McCormick Observatory and professor of practical astronomy in the University of Virginia from 1882 until 1912, on January 17, aged eighty-six years.

Sir J. Arthur Thomson, formerly regius professor of natural history in the University of Aberdeen, who was widely known as a writer and lecturer on natural history, on February 12, aged seventy-one years.

News and Views

Gold in Kenya

THE debates on the amendment of the Kenya Native Lands Trust Ordinance in both Houses of Parliament on February 8 did little to remove apprehension as to the manner in which the exclusion of land from the reserves is likely to affect the native population. The motion for papers moved by Lord Lugard in the House of Lords was withdrawn; and the amendment of Mr. Lunn to Mr. Donner's original motion, approving the action of the Government of Kenya in the steps taken to develop the goldfields and safeguard the interests of the natives, was defeated by a majority of 151. The case against the amendment of the Ordinance, as accepted by the Kenya legislature, was stated lucidly by Lord Lugard, who was ably seconded by the Archbishop of Canterbury; while in the House of Commons Sir Robert Hamilton gave an emphatic, but temperately phrased, expression to the feeling of uneasiness which has been aroused by the manner in which the Government has handled the situation. It cannot be said that the Government has given a satisfactory reply to its critics. The main contention, that the exclusion of land from the reserve without a compensating grant of additional land is a breach of faith and will be detrimental to tribal life, has not been met. However convincingly it may be argued on this ground or on that that there has been no real departure from the undertaking of the Ordinance, either in letter or in spirit, it is the native point of view that counts in this connexion. As Sir Robert Hamilton said, if the confidence of the native in the good faith of the Government be shaken, "in the long run we shall lose more than will be repaid by all the gold in Africa".

THE voting in the House of Commons was no doubt largely affected by the stress laid by Sir Philip Cunliffe-Lister on the small number of individuals and the relatively small area of land affected by the present proposals, as well as by the anxiety of the Government and of the local administration to make it clear that it is their desire not only that the native should not suffer, but rather that he should benefit from the stream of prosperity which will flow in his direction. On these points two comments may be made. First, that it was unfortunate that Sir Alfred Kitson's report on the applications for concessions now under consideration did not come within the terms of the debate. This report shows that ultimately an area of at least five thousand nine hundred square miles will be in question; and now it would appear that part of Kikuyu may be affected. On what terms will the development of these areas be undertaken? Secondly, a prosperity which is detrimental is illusory. The prosperity to come was contrasted by one speaker in the House with the miserable conditions of the natives to-day. But if, apart from a temporary economic crisis, the present-day conditions are in harmony with tribal traditions, a sudden accession of prosperity, for which the social organisation is not yet ready, will give rise to graver problems, similar to those now the cause of anxiety elsewhere in Africa. We are asked to trust the goodwill of those on the spot, whose relations with the native are said to be excellent. Goodwill is of little avail when question arises of interference with native custom, unless it accompanies scientific knowledge, such as can only be gained, as any anthropologist will point out, after prolonged and intensive study. Without such knowledge, modification of tribal custom always involves the danger of detriment to the social organism as a whole. Yet it is on the preservation and gradual development of that organism that the future of the native population depends.

New Record for Non-Stop Flight

A FAIREY long-range monoplane (Napier Lion engine), flown by Squadron-Leader O. R. Gayford and Flight-Lieut. G. E. Nicholetts, beat the world's long-distance non-stop flight record on February 6–8, flying from Cranwell, Lincolnshire, to Walvis Bay, 781 miles north of Cape Town. The distance of 5,340 miles was covered in 57 hours 25 minutes. The previous record was 5,012 miles from New York to Constantinople. The machine followed approximately the shortest great circle course, making detours to avoid the Atlas mountains in Northern Africa and the Ahaggar plateau in Central Sahara. The ideal weather conditions of a westerly wind at Cranwell for take off, and a following northerly wind for the rest of the journey, with clear weather and a full moon over Africa, were experienced for the first part of the journey. Later, unfavourable weather and winds over Nigeria and Duala hindered progress sufficiently to make it impossible to reach Cape Town because of lack of petrol and the approach of dusk.

As equipped for this flight the monoplane carried about 8,000 lb. of petrol and weighed about 17,000 lb. total weight. A specially prepared run-way of one mile was used at Cranwell, the machine running 1,600 yards in 58 seconds before taking off. It was fitted with an autogyroscopic control which not only relieves the pilot of the strain of continuous flying, but assists accurate course keeping. This broke down during the latter part of the flight. A short wave (33·71 cm. wave-length) wireless transmitting set was used to report progress but no receiving set was carried. This gave variable results; messages were picked up over considerable distances but some were undecipherable. The flight was carried out by the Royal Air Force as part of a general policy of development of long-distance air transport for strategic purposes. Not only will the behaviour of the aircraft, engine and instruments be carefully examined, but the medical department is investigating the effects of such flights upon the personnel engaged. The special food carried was chosen by the medical authorities.

John Thompson

CHARLES HUTTON, when engaged in editing the "Diarian Miscellany" in 1775, regretted the insufficiency of biographical material for the lives of the mathematicians responsible for the problems that appeared every year in the eighteenth century almanacks known as the "Gentleman's" and "Ladies'" "Diaries", which were edited by Henry Beighton of Griff from 1714 until 1744, with the assistance of Anthony Thacker, and later by Robert Heath, 1745–53. One of their collaborators was John Thompson of Witherley Bridge in Leicestershire, the hundred and fiftieth anniversary of whose death falls on February 25. By good fortune his surveying instruments, until recently in the possession of his descendant, Mrs. Alkin of Atherstone, are still extant and have been presented by the Friends of the Old Ashmolean to the Lewis Evans Collection at Oxford. They show that Thompson was a practical inventor and improver of instruments as well as a mathematician. It is stated in Nichol's "History of Leicestershire" that Thompson, on leaving Atherstone School, had been intended by his father for the farming and grazing business, but the boy's innate love of mathematics was so strong that, with the collusion of his mother, he surreptitiously purchased a few mathematical books and studied them where and when he could, generally at night. He was helped by Beighton and Thacker, and contributed articles to various journals. When Atherstone common fields were enclosed in 1765, an error by the Commissioners led him to propose a prize question (No. 290) in the "Gentleman's Diary" for 1766. It had been agreed that the small cottages should have a plot known as Cottagers' Piece in the shape of two trapezia to contain 100 acres. Thompson was asked to resurvey it and found it three acres too large, on which he based his prize question, as he said, "that the error of these unmathematical Bunglers may be known".

THOMPSON'S instruments include two levels by Thomas Wright, one dated 1724, a cross head by J. Scarch with one quadrant graduated, an early Gregorian telescope, chains, and the usual slide rules, scales and drawing instruments, and, most interesting of all, a superb plane-table and tripod designed by John Thompson himself, and inscribed "Made by G. Adams in Fleet St. London. Inst: Makr: to His Royal Highness the Prince of Wales." It is surrounded by inlaid brass scales, and measures 18½ in. across.

By a special tilting arrangement the table can be adjusted at any desired angle. It is provided with marginal sights, and adjustable rules which can be raised by screws or depressed level with the surface of the board. The magnetic compass box is of the shape of a figure 8, and the card is only graduated for 45° on each side of the north-south line. It is the most perfectly designed and executed plane-table which we have seen. Two note-books show that he was instructing his sons Ralph and Samuel in the art of surveying in 1773 and 1778 respectively. Ralph Thompson also became an accomplished surveyor, and an example of his work made in 1812, a survey of the Roman town of Manduessedum on Watling Street, is reproduced in Nichols's "Leicestershire".

Nest-Building of Brush-Turkeys

An early visit to the gardens of the Zoological Society of London is recommended in order to inspect the initial stages in the nest-building of the brush-turkeys, on the north bank of the Canal. The labour of forming the vast mound of leaves, in the centre of which the eggs are laid, is performed by the male. Here they are left until they hatch by the heat generated by the fermentation. The eggs being of great size in proportion to the size of the bird, the early, 'nestling-down', stage is passed within the shell, the down being shed before hatching. By the time this takes place the birds are strong enough to force their way out, and emerge with fully developed flight-feathers. This singular phase in the infancy of birds is confined to the Megapodes, of which there are many species. But some bury the eggs in hot sand, instead of decaying vegetation. The recently added 'piping-crows' from Australia, which are more nearly related to the drongos and swallow-shrikes than to the crows, and that singular fish the climbing-perch (*Anabas*), are also worth a visit.

Physical Nature of the Nerve Impulse

AT the Friday evening discourse held at the Royal Institution on February 10, Prof. A. V. Hill discussed the physical nature of the nerve impulse. The properties of the nervous system are based upon a certain transmitted wave which is known as the nervous impulse. This wave, which is a few centimetres long, travels in nerve fibres of the order of 0·01 mm. in diameter with velocities varying from a few centimetres to 100 m. per second. Its nature is not yet understood, but it possesses certain well-defined physical characteristics. The chief difficulty in investigating it is the minuteness of the changes involved in its passage: there is, for example, a rise of temperature, but this is only of the order of one ten-millionth of a degree for each impulse, while the chemical changes which accompany this are at present altogether beyond detection. Fortunately, owing to the development of modern electrical methods, the electrical accompaniments of the wave can be accurately recorded, and the study of the so-called 'action current' has thrown much light on the process. The nature of electrical excitation has been discussed for many years, and it seems that 'activity' is produced when the current through the nerve fibre surface exceeds a certain value at the cathode. The 'activity' seems to consist of an alteration in the physico-chemical properties of the surface layer, allowing reaction to take place momentarily between inside and outside. The change is rapidly reversed, and the nerve is then ready to transmit another impulse. The passage of the wave involves the liberation of energy during, but chiefly after, the active process. Recovery lasts 30–50 minutes and requires oxygen. In other respects, however, the nerve impulse possesses wave-like properties, and its further investigation by physical means is likely to lead to a far greater understanding of nervous processes and of the phenomena of living activity in general.

Scientific Progress and Ethics

IN the *Journal of the University of Bombay* (Sept. 1932), under the title "Is Man Ethically Fit for the Bounties of Science?" Prof. D. D. Kanga of Gujarat College, Ahmedabad, comments on a convocation address by Sir C. V. Raman on the study of science. Asserting that true scholarship goes hand in hand with research, independence of thought and original thinking, Sir C. V. Raman said that the function of a university is the encouragement of the human intellect and the human spirit in their highest manifestations. The greatest value of science lies not so much in the imparting of knowledge about natural phenomena and the laws of Nature, as in the teaching of the scientific method which has served as a powerful weapon in the hands of man in the discovery of truth and has given him a new view of the universe he lives in. If the same method were used in the problems of daily life, whether political, industrial, social, educational, or religious, it would usher in a new era of progress and enlightenment in all the departments of life. Prof. D. D. Kanga, reviewing the sabotage which has accompanied increased productivity consequent upon the application of modern science, directs attention once more to the problem of distribution, which he reminds us is largely a matter of the individual will. It is the duty of every university to see that the advance of science and the spread of scientific culture go with a parallel advance in man's ethical and spiritual development. The motto of science should be truth and service, and the alumni of a university should be characterised alike by their ability to apply the scientific method in all problems of life and also, in Prof. Kanga's view, by their readiness to share their knowledge, wealth, power and possessions with others, of whatever race or country, for the common good.

Persepolis

THE archæological expedition to Persepolis of the Oriental Institute of the University of Chicago, one of the eleven expeditions of the Institute now at work in the East, has achieved some remarkable results in its second season's work on the site. Indeed, Dr. J. H. Breasted, director of the Institute, in a comment appended to an abstract of the report by

Dr. E. Herzfeld, field director, which appears in the *Times* of February 4, says that no discovery like it has ever been made anywhere in western Asia. A magnificent series of sculptures, dating back to the time of Cyrus, has been discovered in the area of the palace burnt by Alexander the Great in 330 B.C. The size alone, without taking into account the technique and the informative detail, is overwhelmingly impressive. One panel, 5–6 ft. high, is no less than 1,000 ft. long. The carvings are as fresh as when executed and show rulers, footmen, horsemen, charioteers, servants and burden-bearers in full equipment—material of the greatest historical value. One panel preserved in peculiarly favourable circumstance still shows the colours of the royal garments. A find of no less importance to the prehistorian is recorded in an account of a stone age village which was found under a low mound within two miles of Persepolis. It is dated at about 4000 B.C. and would appear to be in an excellent state of preservation. The mud-brick walls of the houses still stand to a height of 5–7 ft. and the interior surfaces show mural paintings in red water colour. The polychrome pottery, Dr. Herzfeld reports, exceeds in beauty and age that found in Babylonia, marking "a new chapter in the history of prehistoric art".

International Congress of Ethnological and Anthropological Sciences

CONSIDERABLE progress has been made in the discussion of the proposal to institute an international congress of the ethnological and anthropological sciences. Arrangements are now being made for a preliminary conference for further discussion to be held in Basel on April 20–22 next. Invitations to the conference are being issued by the Royal Anthropological Institute of Great Britain, while the local arrangements are in the hands of Dr. Felix Speiser, director of the Museum of Ethnology, Basel. The conference will be welcomed on behalf of the City and the Education Committee, and its sessions will be held in the Burgeratsaal. The subjects for discussion by the conference are the scope of the proposed congress and its relation to existing congresses of like character, such as the International Congress of Americanists and the International Congress of Prehistoric and Protohistoric Sciences; constitution and procedure; and the date and place of the first meeting. On this last point, it has been suggested that meetings should take place in years alternate to those of the Prehistoric and Protohistoric Sciences Congress and coinciding once in every four years with the European meetings of the Americanists' Congress.

Insect-Eating in Siam

INSECT-EATING habits of monkeys have persisted, and still persist, not only amongst the most primitive races of mankind, like Australian aborigines and the African pygmies, but even in many races which have reached the agricultural stage. An interesting example is offered by the Laos of Siam, whose habits of eating insects and other invertebrates have been recently studied in some detail by Mr. W. S. Bristowe (*Trans. Entom. Soc. Lond.*, 1932). The list of animals used as food by the Laos includes many species and exhibits a great variety, but certain of them are considered as special delicacies. Here belong, for example, giant water-bugs (*Lethocerus indicus*), measuring about two inches in length and fetching up to 4*d.* a piece on the markets; large spiders, *Nephila maculata* and *Melopoeus albostriatus* ('bird-eaters'); eggs of king crab, *Tachypleus gigas*, which look like caviare, but taste like potato; larvæ, pupæ and adults of the dung beetles, *Oryctes rhinoceros* and *Helicopris sp.*; a large cicada, *Dundubia intemerata*; etc. There is no reason to think that insect-eating habits of the Laos were acquired owing to the lack of other food, since the Siamese living under the same conditions do not eat insects to such a great extent. On the other hand, it is interesting to note that the Laos are considered to possess greater stamina and to be harder workers than the Siamese; this may be due to the extra protein obtained by the Laos from their animal food. The average diet of a Siamese includes fish as practically the only source of protein; the protein content of fish is 18–23 per cent, and that of roasted spiders is so high as 63·4 per cent.

Fauna of the Swiss National Park

THE area of mountain, forest and valleys comprising the Nature reserve which forms the Swiss National Park is a tract of country that is rigidly preserved. Its fauna and flora are subjected to the minimum of interference on the part of man and for this reason afford many problems of special interest to the biologist. Under the auspices of the commission for the scientific investigation of the Swiss National Park, a series of quarto memoirs on researches undertaken in that area is being published. The sixth memoir in that series has recently come to hand and deals with the forest insects of the Park ("Les Insectes Forestiers du Parc National Suisse". Pp. 50 + 24 plates. Aarau: H. R. Sauerländer et Cie. 12 francs). Its author, Dr. Aug. Barbey, mentions that the circumstances in which these insects were studied were purely economic and were in connexion with the ravages they cause among the forest trees. The life-history, mode of life and economic status of the more important species of insects are described. Various stages in their life-cycle, their larval burrows in wood and bark and other phases of these insects are admirably portrayed in the series of plates that accompany this memoir. Their ecological relations are also dealt with whether they be destructive forms, parasites or predators.

Reduction of Chimney Emissions

THE Technical Committee appointed by the Electricity Commissioners in 1930 to consider the methods that should be taken to prevent the emission of soot, ash and grit from the chimneys of electric power stations has now published its report (London: H.M. Stationery Office, 5*s.*). A sub-committee made a thorough investigation, visiting many foreign stations which have adopted preventive measures. In 46 of the 111 British selected stations no grit extraction plant has yet been installed. The subcommittee regards grading by sieves as unsatisfactory, as it is impossible when the mesh is too small and untrustworthy for larger values. Particles below 20 microns (1 micron is a thousandth part of a millimetre) when discharged into an air stream are sufficiently diffused to avoid creating a nuisance. The only satisfactory way of testing the efficiency of dust extraction plant is to weigh the dust in unit volume of the gases at as high a point in the chimney as practicable. In Germany, where the power stations are generally larger than in Great Britain, electrostatic precipitation together with very high chimneys is favoured. The main conclusions arrived at by the Committee are that dust nuisance is avoidable with new stations, but the application of means for its prevention to all existing stations may not be practicable. There is an urgent need for standardisation of good methods of testing dust extraction plant. For pulverised fuel installations the electrostatic precipitator is the most suitable type to use. Water for dust extraction is not to be commended. The minimum height of chimneys should be at least two and a half times that of the highest point of the generator station buildings. Photographs are given of the filters used for separating ash and grit particles and of plant for multiple-cyclone dust extraction.

Gaseous Tubes for Lighting

THE study of the discharge of electricity through gases has led to many important practical developments, the latest being the invention of vacuum tubes for lighting. If discharge tubes are filled to the same gaseous pressure with different gases such as helium, neon, argon, hydrogen and nitrogen, it is found that a certain definite voltage must be applied to the terminals of the tube before luminous effects are produced. This voltage depends on the nature of the gas and the pressure in the tube. In general, neon produces a luminous effect at lower voltages than the other gases and then comes helium. In some cases a mixture of gases becomes luminous at a lower voltage than any of the pure gases forming it. In a lecture to the Preston Scientific Society given on December 2, 1932, J. N. Addington gave an interesting account of the progress made in developing gaseous tubes for lighting and signalling purposes. In an Osglim lamp, which takes only a small fraction of the power taken by a filament lamp, the electrodes are of nickel or iron placed about 2 mm. apart and the neon gas filling has a definite low pressure. At 160 volts the lamp becomes luminous. These lamps operate from alternating current mains. Neon valves which operate traffic signal devices have now been developed at the Preston lamp works of Messrs. Siemens Brothers and Co. The red neon signs which are now familiar to all dwellers in cities have iron or nickel electrodes and the illumination is produced from the positive column. The intensity of illumination per unit area is relatively low in these lamps, which are called cold cathode tubes. In 'hot cathode tubes' currents nearly a hundred times as great can be obtained. The electrodes are coated with mixtures of alkaline earths and have a very high electronic emission when heated to 1,200° C. The use of metallic vapours like sodium, cadmium and magnesium has still further increased the efficiency of these tubes, but the colours at present obtained leave much to be desired when compared with daylight.

Gifts to Science

SIR DUGALD CLERK, who died on November 12 (see NATURE of December 24, p. 953), bequeathed £3,000 to the Institution of Civil Engineers; £2,000 to the Royal Society; £1,000 to the Royal Institution; £1,000 to the Royal Society of Arts; £1,000 to the Institution of Mechanical Engineers; £1,000 to the University of Glasgow; £1,000 to the University of Leeds; £1,000 to the University of St. Andrews; £1,000 to the University of Manchester; £1,000 to the University of Liverpool. The residue of the property is to be divided into thirty-one parts; three of these parts are to go to the Institution of Civil Engineers; two to the Royal Society; one to the Royal Institution; one to the Royal Society of Arts; one to the Institution of Mechanical Engineers; and one each to the Universities of Glasgow, Leeds, St. Andrews, Manchester, and Liverpool.

Entomological Society of London

THE Entomological Society of London will celebrate its hundredth anniversary on May 3, and a preliminary programme of the centenary celebrations on May 3-4 has recently been published. On May 3, a general meeting will be held in the rooms of the Royal Geographical Society at 3 P.M. and a scientific conversazione at 8.30 P.M. A reception has been arranged for May 4 at 9.30 P.M. This will be held at Lancaster House, St. James's, S.W.1, when the Right Hon. Walter Elliot, Minister of Agriculture and Fisheries, will receive the guests. Further information can be obtained from the Secretary, 41 Queen's Gate, London, S.W.7.

Chadwick Public Lectures

THE next series of Chadwick Public Lectures begins on February 21, with a discourse on "The Hippocratic Tradition" by Dr. Matthew B. Ray. The lecture will be given in the hall of the Royal Society of Tropical Medicine, 26 Portland Place, W.1, at 5.15. The second lecture will be given by Dr. E. Killick Millard on "Housing", on March 9 at 8 P.M. at the Royal Sanitary Institute. How to secure a pure milk supply is the question chosen by Dr. J. Walter Carr, for his lecture—"Cows' Milk" in March at the Royal Society of Tropical Medicine. In it, he will discuss the relative benefits of human and bovine milk for infants, the value of milk in adult life and how to render cows' milk a safe food. In May, Mr. P. W. Coombe will lecture on "Port of London Sanitary Administration". The actual processes and details of the organisation and maintenance of port and river hygiene will be discussed. Another lecture projected for May will be on the "Preservation of Health in the Navy" by Vice-Admiral Bond, and early in June the annual open-air lecture in the Chelsea Physic Garden will be given by Prof. J. G. Hill, on "The Green Leaf". Further information concerning these and other Chadwick public lectures can be obtained from the Secretary, The Trust Office, 204 Abbey House, Westminster, S.W.1.

Climate of Hong-Kong

COL. E. GOLD points out that, in the article entitled "Climate of Hong-Kong" (NATURE, Jan. 21, p. 104) the statement "much of it [mist and fog] is due to dynamical cooling of advancing damp southerly winds" requires amplification. Damp air moving from the south and rising to the higher levels of Hong-Kong about 1,500 ft. above the level of the Observatory and 1,600 ft. above sea-level is cooled by expansion as it rises and so causes much of the fog and mist at these higher levels. The fog and mist at sea-level, when it occurs with a warm southerly current of air, is due to the cooling of this current by the surface of the sea — or the surface of the land.

Announcements

THE Council of the Iron and Steel Institute has awarded the Bessemer gold medal for 1933, to Dr. W. H. Hatfield, director of research in the firm of Messrs. Thos. Firth and John Brown, Ltd., in recognition of his distinguished services in the advancement of metallurgical science, and of his valuable researches in connexion therewith.

HIS MAJESTY THE KING has approved the award of the Royal gold medal of the Royal Institute of British Architects to Sir Charles Peers, president of the Society of Antiquaries and chief inspector of ancient monuments and historic buildings, in recognition of his distinguished services to architecture and archæology.

THE annual May lecture of the Institute of Metals will be delivered on May 10 by M. Albert M. Portevin. The subject of the lecture will be "Quenching and Tempering Phenomena in Alloys". It is also announced that the silver jubilee meeting of the Institute will be held at Birmingham on September 18–21.

THE Sir Henry Trueman Wood memorial lecture of the Royal Society of Arts will be delivered on February 22, by *Sir William B. Hardy*, director of food investigation, Department of Scientific and Industrial Research, who will take as his subject "Industrial Research with Biological Material".

IT is announced in *Science* that F. Trubee Davison, Assistant Secretary of War in charge of aeronautics, has been elected president of the American Museum of Natural History to succeed Prof. Henry Fairfield Osborn. Prof. Osborn, who has been president of the Museum for twenty-five years, has been elected honorary president.

AT a meeting of the International Congress of Americanists in La Plata in December last it was resolved that the next meeting of the Congress, which, under the statutes, must be held in Europe in 1934, should take place in Spain. It was decided that an invitation to hold the Congress in Seville be accepted.

AT the annual meeting of the Royal Astronomical Society held on February 10, the following officers were elected: *President:* Prof. F. J. M. Stratton; *Vice-Presidents:* Sir Arthur S. Eddington, Mr. John Evershed, Dr. H. Knox-Shaw, and Dr. W. J. S. Lockyer; *Treasurer:* Mr. J. H. Reynolds; *Secretaries:* Mr. W. M. H. Greaves and Dr. W. M. Smart; *Foreign Secretary:* Prof. Alfred Fowler.

THE annual meeting of the Association of Technical Institutions will be held at the Cordwainers' Hall, Cannon Street, London, E.C.4, on February 24–25, under the presidency of Sir Hugo Hirst. Several papers of technical interest will be read at the meeting and a discussion on "Policy in Technical Education" will be opened by Dr. Percival Sharp and summarised by Principal J. C. Smail. Further information can be obtained from the Secretary, Association of Technical Institutions, Loughborough College, Loughborough, Leicestershire.

A GENERAL discussion on "Liquid Crystals and Anisotropic Melts" has been arranged by the Faraday Society and will be held at the Royal Institution, Albemarle Street, London, W.1, on April 24 and 25. The introductory paper will be given by Prof. C. W. Oseen (Uppsala). The following foreign visitors will contribute papers: Prof. L. S. Ornstein and Dr. W. Kast (Utrecht), Prof. V. Freedericksz (Leningrad), Prof. M. Jezewski (Cracow), Prof. G. van Iterson (Delft), Prof. D. Vorlander (Halle-on-Saale), Prof. H. Zocher (Prague), Prof. K. Hermann (Berlin-Charlottenburg), Prof. T. Rinne (Freiburg i. Br.), Prof. G. Foëx (Strasbourg), Prof. G. Stewart (Iowa), and Prof. J. J. Trillat (Paris). Prof. Hermann Mark (Vienna) and Dr. E. Friedel (Strasbourg) also hope to attend the discussion. The meeting is open to non-members.

A SERIES of eight lectures and demonstrations on tropical hygiene, which are intended for men and women outside the medical profession proceeding to the tropics, will be given by Lieut.-Col. G. E. F. Stammers at the London School of Hygiene and Tropical Medicine on March 6–15. This course, in addition to providing simple rules for guidance in regard to personal hygiene and preparation for life in the tropics, will also embrace a short account of some of the more common diseases, with advice in regard to measures of protection and self-treatment. Further particulars can be obtained from the Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant lecturer in engineering at the University of Manchester—The Registrar (March 1). A staff lecturer and demonstrator (woman) in the Department of Chemistry at the Royal Holloway College, Englefield Green, Surrey—The Principal (March 15).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Electron Diffraction by Films of Grease

IN the course of some experiments on the diffraction of electrons by thin films of spluttered platinum, a curious pattern of straight lines with a few diffuse spots (see Fig. 1) was observed by one of us, quite unlike the usual circles of a Debye-Scherrer pattern.

Further investigation has recently shown that it was due to the accidental presence of a layer of tap grease on the specimen. A number of waxes and greases give similar effects when smeared on to a solid and used to reflect a beam of electrons.

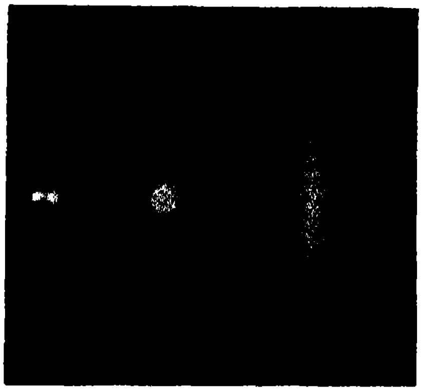

FIG. 1.

The patterns observed can be explained by supposing that the diffracting atoms occur in regular layers parallel to the surface, the layers being equally spaced, but the atoms in each layer being almost at random. Such a distribution would be produced by long-chain molecules normal, or equally inclined, to the surface, like those studied by N. K. Adam. The successive layers are the planes through successive carbon atoms of the chain. It will be noticed that alternate lines are darker than the others; this may be due to the zig-zag nature of the carbon chains which makes alternate atoms different from their neighbours. The spacing corresponding to the distance between a weak and strong line is 2·54 A. which agrees well with Müller's value of 2·537 A. for the distance between alternate carbon atoms.

Sometimes spots appear on the lines. These can be explained as due to a quasi-regularity of arrangement of the chains such as would occur if they were closely packed together.

The distance apart calculated on this assumption agrees fairly well with the cross section found by Müller.

Convention and Fact

THE work of electrical commissions was one of the first, and remains one of the most successful, examples of international co-operation. The main reason for their success, where so many analogous bodies have failed, is that they confined themselves strictly to the establishment of conventions concerning matters (such as units and symbols) to which conventions are appropriate. Dr. Ezer Griffiths's article in NATURE of December 31, p. 987, shows that the International Union of Pure and Applied Physics does not intend to be bound by any such limitation. Although the title of his article suggests that its inquiries concern only units, it is plain that the Union proposes to discuss, if not to decide, matters of an entirely different nature, to which the conceptions of truth and error are applicable. This new policy demands far more attention than he has given to it.

Dr. Griffiths's second issue does, indeed, involve a matter of pure convention. It is agreed that there are at least two distinguishable magnitudes to which the name *permeability* and the symbol μ have been attached by various writers in the past. Everyone would welcome a decision to which of these magnitudes the name and the symbol are to be confined in the future, and a suggestion for the name and the symbol to be used for the others. But Dr. Griffiths, in stating this issue, asserts by implication two propositions that are not universally accepted and the validity of which is not a matter of convention. They are (1) that every quantity either has dimensions in length, mass and time or is a pure number, (2) that quantities not of the same kind have different dimensions. If it decided that these propositions were true or false, the Union would go far outside the sphere to which its predecessors have confined themselves. But I will not insist greatly on this matter, because it is not clear that the Union is really proposing to make such a decision; the propositions may have been introduced without authority by Dr. Griffiths in an attempt to state the issue concisely.

But there is no doubt of this kind about the first issue. The Union most certainly is trying to establish "a basis on which a connected account of electromagnetic phenomena should rest". For what purpose is this connected account required? Is it education, the statement of a logically complete theory, the formulation of 'consistent' units, or the experimental identification of the units formulated? Is it certain that a single connected account will serve adequately each and all of these purposes? Must the lecturer in electrical engineering work to the same syllabus as his colleague who is instructing mathematicians; and are the Diracs and Eddingtons of the future (or even of the present) to be forbidden to choose a 'starting point' for a theory of the universe inappropriate to immature minds? And what is a connected account? An answer to that question can only be based on some view of the logical structure of science, of the relation between fact and theory and between experiment and calculation. It must involve a choice between the views of this difficult matter taken by (say) Jeffreys, Reichenbach and Bridgman; none of these writers could possibly accept a connected account drawn up by another.

I submit that an International Union can do nothing but harm in even discussing questions that require a decision on such matters. An authoritative committee is the right body to establish a convention, because in conventional matters agreement is more important than any kind of truth. Of course there may be differences of opinion as to which convention is best; but the establishment of a convention does not require the acceptance of the committee's views on this point. A convention might be defined as something that a reasonable and conscientious man can accept and support loyally, although he believes that it is the worst of all possible alternatives. But where truth is more important than agreement, a committee can achieve nothing. If agreement actually exists, its pronouncements are superfluous; if it does not exist, a pronouncement, however authoritative, will not bring it into being. In spite of the increasing weight of authority in the realms of politics and religion, most scientific workers would surely still not deny that even an International Union may sometimes be unable to arrive at the truth.

It will be replied, I suppose, that the Union does not pretend to decide any of these questions, and that it is merely collecting the best opinion concerning them. If that is so, what does Dr. Griffiths mean by saying: "The British view is that . . ."? The discussion of the British National Committee apparently took exactly the course that might have been anticipated. Those who were known to have definite views on these matters each brought forth his 'King Charles's head' and said exactly what was expected of him. Those who had not thought about them deeply before offered opinions that really could not stand any serious argument. The publication of the whole discussion might possibly serve some useful purpose; but the selection from it of a "British view", formulated without argument, can lead to nothing but disaster. It is quite certain that the "views" of some other nations, formulated in the same manner, will differ from the British view; only two consequences can then follow. A fictitious agreement will be reached which will involve the public profession by some members of the Union of views on scientific questions that they do not really believe; or no agreement will be reached, and the cause of international co-operation will receive another setback from the failure of yet another conference—and all because the leaders of the scientific world cannot distinguish between convention and truth!

Components of the Atmosphere and Synthetic Gases in Relation to Animal Life

IT was found several years ago in our experiments that small animals such as rats, pigeons, cats, guinea pigs, monkeys, etc., can live in a medium of air under control, but cannot live in pure oxygen under similar conditions, but will die within two to five days[1].

With a synthetic mixture of 79 per cent nitrogen and 21 per cent oxygen leaving out the 1 per cent rare gases such as argon, helium, neon, krypton, and carbon dioxide, it was found that the animals (white mice) would die within ten days to three weeks. The experiments were repeated ten times. These experiments led to the conclusion that the rare gases are vital to the normal respiration of life. By varying the percentage of oxygen from 25 to 60 with nitrogen the animals were under control from ten days to three weeks without any signs of ailments. In a number of cases it was found that synthetic atmospheres could be prepared that supported life in white mice more effectively than the normal air that we breathe every day.

For different gases alone it was found in a series of experiments that animal life would cease after two to five days in pure oxygen; in pure hydrogen, 36 minutes; in nitrogen, 6 minutes; in argon, 3 minutes; in neon, 1 minute and 40 seconds; in helium, 2 minutes and 40 seconds; in nitrous oxide, 10 minutes; and in carbon dioxide, 55 seconds.

By using 79 per cent helium instead of nitrogen and 21 per cent oxygen, an atmosphere is formed in which animal life will exist normally, or in some cases, apparently better than in a normal atmosphere. By varying the percentage of helium from 79 to 50 with oxygen the animals in every case appeared to be normal or better than in our natural atmosphere.

By using 0·03 per cent carbon dioxide, the amount that is normally present in the atmosphere, with 99·97 per cent of oxygen, the average time of life was found to be about the same as with pure oxygen. With a synthetic mixture of 1 per cent carbon dioxide and 99 per cent oxygen the average time of life was 3 days and 9·8 hours. With 5 per cent carbon dioxide and 95 per cent oxygen the average time of life was 4 days and 10·7 hours; with 10 per cent carbon dioxide and 90 per cent oxygen 2 days and 4·2 hours. The optimum mixture seems to be approximately a mixture of 5 per cent carbon dioxide and 95 per cent oxygen.

The chief principle of this therapy is that of using a mixture of oxygen and carbon dioxide. Carbon dioxide is used to stimulate the respiratory mechanism to full deep breathing, to flush and flood the blood in the lungs with oxygen, and to ventilate out of the blood any volatile toxic substance. To combat respiratory failure in this way is to use Nature's own agency to assist Nature towards recovery. Acapnia or deficiency of carbon dioxide in the blood and tissues, is a condition closely related to asphyxia or deficiency of oxygen in the tissues. Either of these deficiencies disturbs the respiratory processes of the tissues, and each involves a considerable degree of the other. Experimentally, a slight degree of acapnia may be induced by over-ventilation of the lungs. Inhalation of carbon dioxide affects a restoration of the alkali bicarbonates and carbon dioxide content of the blood.

Inhalation of carbon dioxide, by counteracting acapnia and inducing deeper breathing, inflates the lungs and prevents the development of pulmonary collapse (atelectasis). It is thus a specific preventive of the post-operative pulmonary complications that lead to pneumonia.

With all of the synthetic atmospheres experimented upon with animals, oxygen was always found to be necessary as one of the gases, but with oxygen alone, the animals would die.

This is really only one phase of the work that might be investigated. It would be desirable to have some other criteria than life as a test, for example, rate of growth, metabolism, activity, why the animals die in oxygen, etc.

In the field of practical applications of synthetic atmospheres there is a wide range of commercial uses and values. In deep sea diving, mines, and submarines, foul air is encountered and there is often a lack of sufficient pure air to sustain life. Aeronauts may carry a supply of prepared atmosphere aloft with them, and it may be provided for large factory and office buildings with more satisfactory results than when natural air from outside is used.

As suggested by Dr. Edward Fidlar[2] the chemist and physicist understand very little the rare gases in relation to animal life. The use of the oxygen tent in the treatment of pneumonia is a well established medical practice to-day. Other diseases may yield to a helium and argon tent. The widest field probably will be in pathological applications. Research work is just beginning in this direction.

Infra-Red Absorption Spectrum of Nitrogen Dioxide

THE infra-red absorption spectrum of the equilibrium mixture of NO_2 and N_2O_4 was investigated in the region of comparatively short wave-lengths by Warburg and Leithäuser in 1907 and 1909, and again in 1910 and 1913 by von Bahr. Preliminary experiments on the spectrum of nitrosyl chloride indicated N_2O_4 as a troublesome impurity, and it was decided to repeat the earlier work and to extend the observations as far as 18μ.

At room temperature a complicated spectrum with bands at 15·6, 13·4, 7·92, 6·17, 5·75, 3·22, and 2·91μ is obtained. The absorption tube was then placed between the source of radiation and the spectrometer, and heated to 100° C.; the maximum of radiation emission characteristic of this temperature is beyond 20μ, and it was found with this arrangement that disturbances of the thermopile due to fluctuations of temperature in the absorption tube were avoided. The interesting observation was made that all the bands disappeared with the exception of those at 15·6 and 6·17μ, the two latter remaining with undiminished intensity, and having a doublet structure with a separation of 35 $cm.^{-1}$ and 32 $cm.^{-1}$ respectively. They may accordingly be ascribed to NO_2, and the simplicity of the spectrum renders it highly probable that the molecule is rectilinear and symmetrical. The N–O force constant is approximately 7×10^5 dynes per cm., the deformation force constant being some 6×10^{-12} dyne cm., and the calculated moment of inertia is 66×10^{-40} $gm.cm.^2$, with an interatomic separation of 1·1 A. If ν_3 is 6·17μ, and ν_2 is 15·6μ, then the position of the inactive fundamental ν_1 may be calculated as approximately 11·1μ.

Further confirmation of the suggested structure may be obtained in a very neat way. The determined force constant for NO_2 corresponds to a single bond between each oxygen and the central nitrogen atom. If one more electron is available as in the case of the ion $[NO_2]^-$, the previously odd electron takes part in bond formation and we should have double bonds between the central and each external atom, with a corresponding elevation of the force constant to 14×10^5 dynes per cm., and, if the ion preserves the rectilinear structure, the Raman spectrum of the solution of an inorganic nitrite should provide a strong line with a separation giving the frequency of the inactive fundamental. Making the allowance for the difference in the force constants, we can calculate the approximate position of this line as 1328 $cm.^{-1}$, and experimental results show that aqueous solutions of inorganic nitrites have in fact an intense line at 1303 $cm.^{-1}$, the corresponding force constant being 14×10^5 dynes per cm.

Consideration of the manner in which given numbers of electrons available for bond formation may be allotted to definite electronic molecular proper-functions shows that in the case of $[NO_2]^-$, which has eight such electrons, it is probable that alternative states with near-lying energy levels are possible, and that reversion from the rectilinear structure characteristic of the ion in aqueous solution to an isosceles triangular form with a vertical angle of some 120° is rendered easy: the latter seems to be the structure of the ion in the crystalline nitrites.

Finally, where, by the establishment of a covalent link as in the case of the nitro- group, only six electrons are available for binding the atomic centres, the triangular form as above with the obtuse vertical angle (we may call this the SO_2 structure) is obligatory: and Dadieu and Kohlrausch from the results of Raman measurements find that the force constant for the NO link in $:NO_2$ is 9×10^5 dynes per cm. and the angle ONO is approximately 110°. As regards N_2O_4, the structure is probably best represented by Hendricks's suggestion of two plane nitro-groups at right angles to each other.

Unusual Occurrence of Pelagic Organisms

IN NATURE of October 29, 1932, there appeared a letter from Messrs. Russell and Kemp, describing how large numbers of *Velella* and *Ianthina* had been cast up in the late summer, on the shores of Cornwall and south-west Ireland, and commenting upon the causes that might have led to this unusual abundance of planktonic organisms rarely present in the locality described.

It is very curious that far away here in New South Wales, we might have written an exactly similar letter about six weeks ago. Four miles off this coast on one rather calm day, I sailed through literally millions of large *Physalia*, *Velella* and *Ianthina*, and my crew were so intrigued at the sight that they proceeded to catch the *Velella* in cups and jars, whilst endeavouring to escape contact with the dreaded Portuguese man-of-war—not at all an easy matter. The invasion of these pelagic species lasted a fortnight or so, and was so great that the dried bladders of *Physalia* and *Velella* and the blue shells of *Ianthina* strewed the ocean beaches over a stretch of many miles.

It will be noticed that our season was springtime, the English season was summer, but the dates (August in England and October here) not so far apart. Presumably, the explanation of these two unusual occurrences at about the same time (it is years since such an invasion was noted here), is merely coincidence. It is difficult to regard it otherwise, seeing that we are in the Southern Pacific and the British swarms came from the North Atlantic. One *might* wonder whether some peculiar cycle of circumstances had led to an unusual development of the organisms in question in tropical ocean waters, like the numeral fluctuations so well known in more confined terrestrial species. But it is difficult then to account for a simultaneous abundance in species so far removed zoologically as *Physalia* and *Ianthina*.

Perhaps, therefore, we had better assume that the happening is just coincidence due to a like sequence of meteorological conditions in the two regions concerned.

Our Government Meteorologist has very kindly given me a comparison of the winds prevailing off this coast during the past three months with the average of eighteen years. From this, it would appear that sea breezes (winds with an easterly component) were not only more frequent than usual, but also the velocities were greater. Since a tropical current passes southward along the coast of New South Wales, it seems reasonable to suggest that a greater tendency for an easterly surface drift has brought shorewards organisms which are only infrequently stranded in such numbers.

It would be interesting to know whether any similar conditions were noted elsewhere during the year 1932.

RECENT letters by Dr. Kemp and Mr. F. S. Russell[1] and Mr. A. C. Stephen[2] have directed attention to the occurrence of Atlantic organisms on the coasts of Great Britain and Ireland. It may be of interest to add another example to the list. While the Fishery Cruiser *Muirchu* of the Department of Lands and Fisheries was engaged in taking physical observations off the south-west coast of Ireland, fifty miles south-south-west of Fastnet Light, on August 9, 1932, considerable numbers of a large salp, 3-8 cm. long, were noticed drifting a few feet below the surface and some were captured. These proved to be the sexual stage of *Cyclosalpa bakeri*, Ritter. Several other specimens occurred in a tow-netting taken on the same station, and also in another taken seventy miles south-south-west of the Fastnet, suggesting that the shoal may have been twenty miles across. *Cyclosalpa bakeri* appears to be mainly a tropical species and I do not know of any previous record from British or Irish waters.

Another possible indication of abnormal conditions in 1932 was the unusual number of blue sharks (*Carcharias glaucus*) noticed during the same cruise along the south coast of Ireland. Frequently, when the ship was stationary, two or three might be seen swimming round and devouring the offal thrown to them.

Velella was not noted during the cruise in any unusual numbers. A few, living, were seen about thirty-five miles north of Horn Head, Co. Donegal, a few, dead, seventy miles south-south-west of the Fastnet and one, living, thirty miles south of Ballycottin, Co. Cork. It seems probable, judging both from recorded observations and reports received from lay sources which cannot always be verified, that *Velella*, and possibly also *Ianthina*, occurs almost every year off the west coast of Ireland, but it is only when they are drifted shorewards by a favourable wind in unusually large numbers that attention is directed to them.

The assumption is sometimes made that the presence of Atlantic organisms is an indication of an abnormal influx of Atlantic water, and their absence of a contrary condition, but such an inference ought to be received with caution unless supported by hydrographic records. Possibly the abnormality lies in the occurrence of conditions exceptionally favourable to the development of the organisms in some distant locality whence the Atlantic drift is derived, rather than in any acceleration of the drift or recognisable increase in the salinity or temperature of the water impinging on our coasts.

Sexual Reproduction in Copepods

AMONG the lower groups of Crustacea, namely, the phyllopods, cladocera and ostracods, parthenogenesis is a well-known phenomenon and in many cases it is the only one known by which reproduction takes place. It is therefore remarkable that the process has only been recorded once within the free-swimming copepods[1].

Now copepods are probably better known than any other group of Entomostraca, and within it one division at least, the genus *Cyclops*, is remarkable for the cosmopolitan distribution of many of its species. Since resting eggs, which can be hatched from dried mud, and parthenogenesis go so naturally together among the Cladocera and ostracods, one might reasonably expect *Cyclops* to possess both these properties. This would be the simplest way of accounting for this world-wide distribution of the species. A natural conclusion is that parthenogenesis really does occur among copepods but for some reason it has been overlooked, and a considerable amount of evidence should be forthcoming before one can deny its existence.

During the last ten years, breeding experiments have been carried out almost continuously with different species of *Cyclops* at Marlborough, and although parthenogenesis has been sought time after time, it has never been found. The most obvious experiment is that of obtaining a brood of nauplii and separating each at an early stage and rearing them to maturity. This has now been done with several species and in no case has a single female produced living offspring. Eggsacs may be produced, and they nearly always are, but they simply drop off in time and the eggs decompose. On one occasion on looking at my cultures for the last time on the last night of term, I found three female specimens of *Leptocyclops agilis* each with a perfectly normal pair of eggsacs. I was obliged to motor the next day to a place in Sussex, just 150 miles away, but managed to return the same night hoping to see living nauplii. These were not there, but in each case the eggsacs had just fallen off and were lying at the bottom of the vessel where they gradually decomposed.

Yet further evidence is obtainable from direct experiment. A male is placed with a number of adult females which have been isolated from birth, and the male is left with them for a limited period and then removed. In these circumstances it is usual to find that more than one female gives rise to living offspring, and the female may produce as many as three broods of nauplii, but she will cease to function unless coition is again allowed to take place.

From this it seems safe to conclude that in many species of *Cyclops* parthenogenesis has not escaped notice. It does not occur.

[1] Roy, J., "Sur l'existence de la parthénogènese chez une espèce de Copépodes (Elaphoidella bidens)." *C.R. Acad. Sci.*, **192**, 558–575; 1931.

Abnormal Movability of the Heart

IT has been found that 9 per cent of 124 healthy soldiers and 26 per cent of 53 healthy high-school girls possess abnormally movable hearts. The criterion of movability taken was the displacement of heart apex due to change of body posture from standing to right lateral positions plus the displacement due to change from standing to left lateral positions. Frequency distribution as regards the movability is shown in the following table:

Movability in cm.	Frequency	Remarks
1 and 1·5	1	Normal heart.
2 2·5	133	
3 3·5	18	
4 4·5	0	
5 5·5	0	
6 6·5	0	
7 7·5	5	Cor mobile.
8 8·5	6	
9 9·5	6	
10 10·5	3	
11 11·5	3	
12 12·5	2	
13 and more	0	

To this distinctly separated group of abnormal movability of heart, I propose to refer by the term 'cor mobile', although this expression has been assigned to some rare cases of abnormal movability of heart of rather indefinite nature.

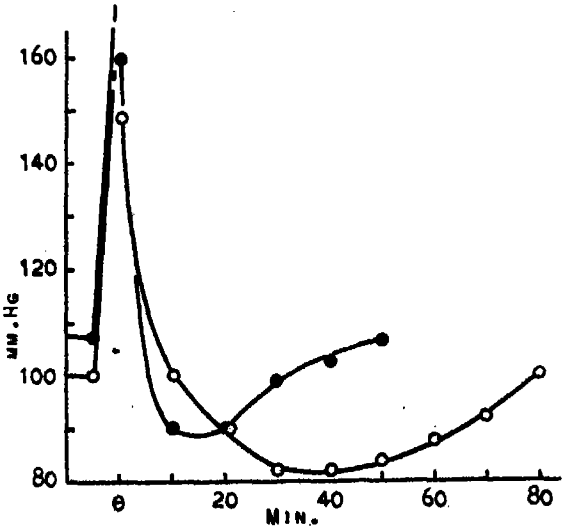

FIG. 1.—Effect on blood pressure by running 100 m. in two cases of 'cor mobile'.

It is interesting to note that the 'cor mobile' individual is liable to show a subnormal phase of blood pressure after strenuous exercise. A group of 14 normal soldiers and another of 14 soldiers with 'cor mobile' were taken at random. After running 100 metres, they were submitted to frequent observations of blood pressure. The result was that 6 out of 14 (43 per cent) normal soldiers showed a more or less marked subnormal phase, while all the 14 'cor mobile' subjects gave a marked, often conspicuous one (Fig. 1). In view of these findings we should like to direct the attention of investigators of the subnormal phase to the fact that the results of experiments may be expected to vary according to the number of subjects possessing 'cor mobile'.

Röntgen photographs of 'cor mobile' are being reproduced elsewhere.

'Raw' Weather

REFERRING to Mr. Beckett's letter in NATURE of January 28, p. 132, by cold moist air I meant air which *feels* moist, and contains particles of water whether visible or invisible. For equal volumes, water has some 3,000 times the thermal capacity and 200 times the conductivity of air. To convert 1 gm. of water at skin temperature into vapour about 600 calories of heat must be supplied. Thus we see how particles of cold mist cool down the skin surface where they touch, and produce the sensation of cold.

Mist and cloud also cut off the radiant heat of the sun. A piece of black fur may be warmed by the summer sun 30° C. more than the air. I found that a coat hung out for four hours in a mist gained 3½ oz. in weight. The water in such damp clothes must be so evaporated by body heat. Thus, as Mr. Beckett says, clothes come into the question. Wet ground is cooled by evaporation, and is not warmed by the sun; and the wind blowing over it is chilly, and entering houses through chinks and crannies may increase the damp of the walls and contents. The cooling power of wind exerted on the body, as shown by the katathermometer, may be very great. Thus a man lying in bed may feel the change of weather

There is, I think, no convincing proof that ionisation or de-ionisation of air such as occurs in ordinary rooms, or out of doors, has any physiological effect. On the other hand, there is abundant evidence that exposure to cold and certain radiations affect the feeling and produce reflex effects on the deeper organs.

Referring to Prof. Russ's letter in the same issue of NATURE, changes of barometric pressure which affect the body equally all over have no mechanical effect upon it. I have observed men under a pressure of even ten atmospheres, and other men, given oxygen to breathe, submitted to a pressure reduced to 170 mm., and no sign of discomfort. Prof. J. Barcroft and his co-workers, however, found that climbing at a pressure of 170 mm. produced pain in the joints, and this in spite of breathing oxygen. The pains, probably, were such as those felt by an athlete after a race, and were due to a local oxygen want. In the case of the athlete, they may be set aside by breathing oxygen before and after the race. At 170 mm., even the breathing of oxygen does not secure a supply sufficient for hard work.

It is probably that local changes of the circulation brought about reflexly by cold, moving, moist air, and want of radiant heat, may produce pain in joints which are not normal, but exposed to some toxic agent the power of which is increased by a lessening of the oxygen supply. In those living a sedentary life, the circulation is very deficient in muscles and joints which are very little used.

Distribution of the Polychæte Worm, *Syllis ramosa*, McIntosh

IT is generally admitted that one of the most remarkable forms of life discovered by the *Challenger* expedition is the polychæte worm, *Syllis ramosa*, in which the body branches laterally, these branches again sending off shoots into the passages of the sponge in which the worm lives. The result is an intricate net-work (except that, of course, the branches do not anastomose), and as each branch ends in an anus there is a large number of ani to one head. The two specimens obtained by the *Challenger* lived in the bases of hexactinellid sponges found at 140 fathoms depth in the Arafura Sea and in the Philippines at 95 fathoms.

Mr. C. C. A. Monro of the British Museum, in a letter to me, writes: "I have not searched the literature thoroughly but as far as I know, *Syllis ramosa* has not been seen since the 'Challenger' except off the Japanese coast, where it appears to be moderately common. It was found by Izuka in Sagami Bay in about 100 fms. and in Struga Bay in 90 fms., usually in a Hexactinellid sponge (*Crateromorpha meyeri rugosa*)."

Its appearance in the northern Red Sea at a depth of one fathom is therefore worth noting. I obtained it from a small sponge about 10 mm. in diameter which was attached to a dead branch of the coral *Lobophyllia corymbosa*, on the edge of a small coral reef about 100 yd. from the laboratory of the Biological Station of the University of Egypt, at Ghardaqa (known to the oil companies, and marked on some maps, as "Hurghada"), just south of the entrance to the Gulf of Suez.

The method of its discovery is also worth describing, as it is the only way in which the bulk of the smaller fauna inhabiting any material can be obtained. A bucket full of the material, in this case, dead branches of *Lobophyllia*, is kept overnight in water to which a handful of magnesium sulphate is added as a narcotic. This causes burrowing and cranny-loving forms to emerge, and on going over the material, 12 to 24 hours later according to the temperature, these may be rinsed or picked off each piece of stone, shell, coral or wood. At the bottom of the bucket remains a considerable bulk of small life, principally Crustacea and Polychæta, with Mollusca, planarians, small echinoderms, sipunculids, etc. This can be washed in old spirit, decanted from sand, and bottled for future examination. As an indication of the difference which would have been made to the older collections had this method been used, I may mention the Staurocephalidæ, small and particularly beautiful Polychæta, which figure in about one collection in twenty. Here, and elsewhere, I have found them in one or two cases by ordinary collecting, but by 'washing out' I find them frequently in fair numbers. In the present case on finding in my 'washing' two small pieces of *Syllis ramosa*, I worked over the material again and soon found the little fragile siliceous sponge in which is the remainder of the worm. I have not attempted to dissect out the head and have not found any sexual buds, preferring to make a thorough search when I have more material. Of its specific identity with *Syllis ramosa*, I have no doubt.

A Dodecapodous Pycnogonid

IN a letter published in NATURE for July 28, 1910, I directed attention to Prof. E. L. Bouvier's discovery of *Pentapycnon* and discussed its relation to the other two genera of decapodous Pycnogonida. I am now able to announce the even more surprising discovery of an antarctic pycnogonid with *six* pairs of legs.

A few days ago, Sir Douglas Mawson handed over the Pycnogonida obtained on his latest antarctic expedition to be worked out by my colleague, Dr. Isabella Gordon. Among these is a magnificent specimen spanning 19 inches from tip to tip of its outstretched legs. So far as our preliminary examination has gone, it appears to differ from the two species of Decolopoda in no important respect except that it has an additional pair of legs. Exact particulars of the locality where the specimen was taken are not yet available, but it was dredged at a depth of 219 metres in the region of the antarctic lying to the south of Australia.

Dr. Gordon and I propose to describe this remarkable new form in detail elsewhere and to discuss its bearing on the problems of pycnogonid phylogeny. It need only be said at present that it appears to offer no obstacle to the view, which I have previously advocated, that the decapodous (and now the dodecapodous) Pycnogonida have been derived from octopodous forms, and that the Pycnogonida as a whole may conceivably owe their origin to an analogous disturbance of the established metameric pattern of the normal Arachnida.

The Second Piltdown Skull

IN his work on "The Skeletal Remains of Early Man" (Smithsonian Miscellaneous Collections, vol. 83, 1930), Dr. Aleš Hrdlička doubts my statement that the late Charles Dawson discovered the isolated lower molar tooth of *Eoanthropus* with the remains of the second skull in the Piltdown gravel. Fortunately, among old correspondence, I have just found a postcard of July 30, 1915, written by Mr. Dawson, in which he announces his discovery of this molar tooth "with the new series". I have given the postcard to the Geological Department of the British Museum (Natural History), so that the record may be preserved and made available for reference.

Research Items

Eskimo Culture Sequence. Stratigraphical evidence from Point Barrow, Alaska, obtained by the latest Alaskan expedition of the Smithsonian Institution, Washington, D.C., would appear to have gone far towards establishing a sequence of Eskimo cultures and determining the place and character of the 'Thule' civilisation of the eastern Eskimo. Hitherto it has been impossible to investigate the oldest 'ivory' culture of Point Barrow by excavation, owing to the short period during which the waters are open; but Mr. James A. Ford, archæologist of the Smithsonian Institution, elected to stay in Alaska during the winter 1931-32, in order to begin digging in June last as soon as the ground thawed. By excavating the 'ivory' culture burials—the settlements have disappeared owing to land subsidence—and the later settlement-mounds, he found that the 'ivory' culture was immediately followed by the 'Birknirk' culture in the graves and that the 'Birknirk' culture was the oldest stratum in the settlement-sites. It was here followed by a transitional stage to the 'Thule' culture, which in turn was followed by a stage scarcely to be distinguished from present-day Eskimo. It is thus shown that not only is the 'Thule' culture to be derived from the ancient Eskimo, which had been doubted; but also that it is relatively recent, and not, as had been thought, of high antiquity. Now at St. Lawrence Island, the 'Birknirk' culture has been found as a variant sequel to the Old Bering Sea culture, the latter being more usually followed by the 'Punuk' culture, a simpler form, which in the course of many centuries degenerates into the crude art of the modern Eskimo. As Ford found both the Bering Sea culture and the 'Birknirk' stage in the Point Barrow graves, it would appear that here the folk were colonists from the Bering Sea population, especially as an outpost of the 'Punuk' was found as the oldest stage of a settlement about sixty miles from Point Barrow. The details of evidence, upon which the summary of conclusions recently issued by the Smithsonian Institution is based, will be published in full in due course.

The Copper Age in Ancient China. The existence of stone and bronze ages in China has been admitted with certainty but the existence of an intermediate copper age has been questioned. A copper age in Egypt has long been established and it would have been expected that it must have existed in ancient China. In the *Bulletin of the Chemical Society of Japan* (December, 1932), Tsurumatsu Dono has described the chemical analyses of three ancient spear heads which closely resemble the objects recently found on the Yin site in the Ho-Nan province. These contain no appreciable amount of tin, which was detected only by the spectroscope. One specimen was nearly pure copper, with about 3 per cent of lead, whilst two others were lead bronzes, with 22·4 and 26·8 per cent of lead, respectively. If these specimens belong to the Yin dynasty, the copper age existed in that period and was in transition to a bronze age, which passed into an iron age about the end of the Han dynasty. Although Dr. Dono does not refer to the fact, it is significant that these lead bronzes of ancient China are similar to those of Sumerian Mesopotamia, and this would seem to lend support to the suggestion made some time ago that a connexion existed between the Sumerian and ancient Chinese civilisations. Only one specimen contained arsenic, and that only 0·8 per cent, whereas the ancient Egyptian bronzes often contained appreciable amounts of arsenic. All three specimens contained 1–2 per cent of iron.

Vocational Guidance and Health. The *Human Factor*, vol. 6, No. 10, contains an article by Mr. Angus Macrae on "Vocational Guidance and the Health of the Industrial Worker". The writer reviews the rôle of the physician in industry and the whole field of vocational guidance. He urges that the physician should exert a constructive influence and make recommendations based on the examinee's physical capacity instead of merely giving negative advice occasioned by some physical deficiency. Most general practitioners make inadequate, if any, reference to the 'mental' condition of the patient. The recent development of the psychologist's technique and the admitted success of various tests make a clearer diagnosis possible. Mr. Macrae refers to most of the work of importance achieved along these lines, surveys the influence of various specific environmental conditions, and concludes with a plea for greater co-operation between the doctor, psychologist and school staffs. He also recommends guidance for leisure as well as work, a more detailed supervision of the juvenile worker and the extension of vocational advice to those already in industry. The comparatively new idea that the supervisor, no less than the worker, may be a misfit is also stressed.

Development of *Gyrocotyle*. Of 93 examples of *Chimæra monstrosa*, examined by J. S. Ruszkowski (*Bull. Internat. Acad. Polon.*, Sci. et Lettres, B.2 (1931), 1932) in the summer of 1927 and 1929 at the Biological Station at Herdla near Bergen, all but one contained in the spiral valve the unsegmented cestode, *Gyrocotyle urna*. The much convoluted uterus of these cestodes was filled with eggs so that abundant material for the study of the development was available. The egg, which is oval and operculate and contains the egg cell surrounded by numerous yolk cells, develops satisfactorily in sea-water in Petri dishes at laboratory temperature. By about the twelfth day the embryo exhibits feeble movements which gradually become more pronounced and ten crotchets appear at the end of the embryo away from the operculum. About a month after the eggs have been laid, the operculum is raised and the ciliated larva with its ten posterior crotchets escapes. It swims actively at first but its movements become slower and after a day almost cease; the larva can live for six days. Attempts to infect bivalve molluscs with the larvæ were negative. On examination of the contents of the intestine of *Chimæra* the author found four young worms 4–10 mm. long. The extremity of the worm with the sucker has been regarded by some authors as anterior, while others have held that the opposite extremity with the rosette is anterior. The crotchets appear at the end which later forms the rosette and this therefore ought to be regarded as the posterior end.

Trematodes of Marine Mammals. Emmett W. Price (*Proc. U.S. Nat. Mus.*, vol. 81, Art. 13, 1932) has brought together the descriptions of all trematodes recorded from marine mammals, has made emendations or additions to the previous descriptions of ten species, based on examination of specimens, and has described a new genus and two new species. He reports that a specimen from *Orcinus orca* (*Orca gladiator*) so closely resembles *Fasciola hepatica*, except in body size and in having a slightly smaller egg, that it must be referred to this species. *F. hepatica* has been recorded also from *Balænoptera acutorostrata*. The trematodes known from marine mammals comprise 31 valid species belonging to nine families. Keys are given to the families, genera and species, a list of hosts and their trematodes is appended and figures of all the species except one are provided on the twelve plates at the end of the paper.

Bacterial Detoxification. The historical and theoretical aspects of bacterial detoxification have recently been summarised by Robert S. Harris and John W. M. Bunker (*Proc. Amer. Acad. Arts and Sci.*, vol. 67, No. 5, p. 147, June, 1932). A list of the agents that have been found to be detoxifiers is given, with full bibliography. Most of these agents depress surface tension, but detoxification is not considered to be due to this depressant action alone, or to any particular anion or cation, but to the configuration of the molecule as a whole. One of the best detoxifying agents is sodium ricinoleate, and in suspension in a three per cent solution of this substance the *Staphylococcus aureus* does not produce abscess formation, or the tubercle bacillus infect, on inoculation into animals. This protective action against the bacteria is not due to germicidal action of the detoxifiers.

British Columbia Douglas Fir Timber. One of the difficulties which would-be users of Empire timbers, both conifers and hard-woods, have experienced has been due to the absence of grading in imported stocks. In connexion with soft-woods, it is held that the best hopes for a big market lie with British Columbian Douglas fir. The appearance of a small pamphlet (H.M. Stationery Office, 6*d*.), entitled "Empire Timbers for Structural Design. British Columbia Douglas Fir", from the Forest Products Research Laboratory at Princes Risborough, is particularly opportune. This pamphlet directs attention to the developments which have taken place in recent years in the grading of structural timbers in Canada. The closer selection of timber with reference to the occurrence of defects, both natural and accidental, leads to much economy through the use of smaller sizes and longer spans. Probably no other timber has of late received so much attention as Douglas fir, for its characteristics have been studied in the forest products laboratories of Canada and of the United States of America, and its application in industry has been systematically developed by several commercial associations. Special classifications of British Columbian timbers have been made to meet the market in Great Britain and quite recently new grades of Douglas fir have been standardised to meet its particular needs. Tables are included in the pamphlet giving safe loads for each of a number of sections supported on varying spans to assist those who wish to employ Douglas fir as joists or rafters in buildings.

Palæozoic Brachiopods. An important monograph by C. Schuchert and G. A. Cooper ("Brachiopod Genera of the Sub-Orders Orthoidea and Pentameroidea", *Mem. Peabody Mus. Nat. Hist.*, 4, 1, 1932) deals with two extinct groups which are found abundantly in Palæozoic deposits. The Orthoids are the most primitive forms of articulate brachiopods and are considered to contain the stock from which all other articulates have evolved. Thus the Pentameracea and Strophomenacea appear to have been derived from the Orthacea. The authors first give a detailed account of the morphology of the shell in the Orthoids and Pentameroids. The table defining briefly but clearly the numerous terms employed will be helpful to students, but it is to be regretted that the widely used term 'cardinal area' is replaced by 'interarea' and 'palintrope' (apparently synonymous). In the Orthoids and Pentameroids, 135 genera and sub-genera are now recognised. The main part of the work is devoted to the description of these genera and sub-genera, their distinguishing features, phylogeny and distribution, with a list of the American and European species which the authors can definitely assign to each genus. British palæontologists will be interested in the suggestion that the well-known genus *Stricklandia* belongs to the early Rhynchonellacea and not, as hitherto thought, to the Pentameracea. Another work on Palæozoic brachiopods, by C. O. Dunbar and G. E. Condra ("Brachiopoda of the Pennsylvanian System in Nebraska", Nebraska Geol. Surv., Bull. 5, ser. 2, 1932) deals with the Middle and Upper Carboniferous brachiopods of Nebraska but mainly from a faunal point of view.

Submarine Faulting in Kimmeridgian Times. Among the normal sediments of the Kimmeridgian coastal strip of the Helmsdale district of east Sutherland a series of boulder beds is interstratified, the origin of which has long been problematical. A careful redescription of the evidence has been given by Prof. E. B. Bailey and Dr. J. Weir (*Trans. Roy. Soc. Edinburgh*, vol. 57, 1932–33, pp. 429–67), and as a result of their investigation they have reached the conclusion that the beds in question are the result of submarine landslips, precipitated by earthquakes along the line of an adjacent fault, and distributed by tsunamis or tidal waves. The fault-scarp was maintained by intermittent movement of the sea-floor, the aggregate movement exceeding two thousand feet. The Old Red Sandstone exposed in the fault-scarp furnished boulders that exceptionally reached a length of a hundred feet. The scarp separated a comparatively shallow-water facies of rounded pebbles and sand, with brachiopods, sea-urchins, corals, etc., from a comparatively deep-water facies, characterised by mud, with debris of land plants, ammonites, etc. The effects of earthquakes are registered not only by the spreading out of the landslips into graded boulder beds, but also by fissuring of the Kimmeridgian and the production of breccia along the fault. The local movements are shown to be contemporaneous with other movements in Britain. The interpretation of the boulder beds is like that already put forward by Bailey, Collet and Field to account for the Palæozoic boulder beds near Quebec. Other analogues in Britain, Switzerland and the United States are briefly discussed. The paper is an important contribution to world geology as well as a model of geological description and interpretation.

Sources of Light for Interferometer Work. Such work as the determination of the metre in wave-lengths of light demands a source of light which is very homogeneous and capable of exact specification. The Michelson cadmium lamp has been generally used for this purpose, but its manipulation is inconvenient. Messrs. Rolt and Barrell, working at the National Physical Laboratory, have examined the suitability of a new type of lamp for such purposes. The lamp is made by the Osram laboratories in Germany and consists of an A.C. discharge between electron-emitting filaments in argon. Some cadmium is present in the tube and when the lamp is running steadily the cadmium spectrum alone is excited. The spectral lines were examined by a variable Faby-Perot etalon, and within the accuracy possible, which was limited by the temperature control of the latter, no difference could be established between the two lamps when the Osram lamp was run with the (reduced) current of 1 amp. With 2 amp. the blue and green lines showed increased complexity, which may be due to self reversal, and the red line itself showed some evidence of inhomogeneity. The authors intend to repeat the work with an invar mounted interferometer.

Gaseous Combustion at High Pressures. The January *Proceedings of the Royal Society* contains a series of papers on the part played by nitrogen in carbon monoxide and hydrogen combustions. In the experiments made by Bone, Newitt, and Townend, explosions of carbon monoxide-air and hydrogen-air mixtures were made in a wire-wound steel bomb under initial pressures of 500–1,000 atmospheres, and the explosion pressures were recorded continuously by a Petavel manometer. As in previous experiments at lower pressures, a liberation of heat was observed for some time after the explosion of a $CO-O_2-N_2$ mixture, which was ascribed to nitrogen molecules activated by the burning carbon monoxide. This effect reached a maximum for initial pressures of about 500 atmospheres. The explosions, both of hydrogen and carbon monoxide, were slightly slowed by the higher pressures, but a hydrogen-air mixture at 750 atmospheres detonated very violently. At the higher pressures, $CO-O_2$ mixtures containing carbon monoxide to replace the nitrogen of the air—carbon monoxide mixtures deposited some carbon on explosion, presumably because the high pressure favoured the reaction $2CO \rightarrow CO_2 + C$. In a paper by Newitt and Outridge, the formation of nitrogen oxides in $CO-O_2-N_2$ explosions was investigated. The products of explosion were liberated into an expansion chamber by the bursting of a steel disc; and the gases thus suddenly cooled were analysed at leisure. Considerable quantities of nitrogen oxides were found and their formation was greatly helped by raising the pressure. The yield of nitrogen oxides was greatest when the disc burst after the maximum pressure had been attained, and the authors explain the formation of the oxides as due mainly to activated nitrogen produced in the explosion. In the third set of experiments, by Newitt and Lamont, carbon monoxide flames were burnt steadily in oxygen-nitrogen mixtures. Nitrogen oxides were formed, particularly at high pressures. The oxide formation is again ascribed to activation of the hydrogen, the mere temperature of the flame being of comparatively small importance.

Astronomical Topics

Earth's Influence on Sunspots. Many solar observers have noted an apparent earth effect in studying the number of spots that are born or disappear in different regions of the visible disc. Mr. P. R. Chidambara Aiyar, of the Kodaikanal Observatory, has collected all the spots of duration two days observed at Greenwich from 1874 until 1930 (*Mon. Not. Roy. Astr. Soc.*, Dec.); they are 1,395 in number. When plotted, they show maxima near the east and west limbs, and also near the centre of the disc, with minima at the intermediate zones, both east and west. There is also a graph of the longitude of birth of spots of two-day duration, from the Kodaikanal records. This shows a similar arrangement, but the minima are not quite so deep; only 389 spots are available, so the weight is smaller. It is difficult to form any plausible hypothesis to explain the falling off in numbers at the intermediate zones.

Comets. An interesting photograph taken by Prof. van Biesbroeck at Yerkes on November 28 and reproduced in *Popular Astronomy* for January shows the two periodic comets Faye and Brooks within half a degree of each other; Faye is distinctly the brighter, but both are easily seen, and have short tails. Comet Geddes, discovered in New Zealand last June, when near the south pole, has now come north, and was seen at Yerkes on December 18, in spite of moonlight. Observations from Tashkent are also to hand. There is an ephemeris in the B.A.A. Handbook.

Prof. van Biesbroeck also reproduces a photograph taken on December 20 of the new comet Dodwell-Forbes; it was of magnitude 9½, 3′ in diameter, without a stellar nucleus or a tail. The period of nine years, given at first, is too short; it is probably a century or more. Mr. Forbes found this comet on December 15, which was probably before Mr. Dodwell saw it; but it was a public holiday in South Africa (Dingaan's Day) and that caused a delay in circulating the announcement.

The comet was seen in Devonshire with a 3 inch telescope, but is now fading.

Proper Motions in the Lund Zone of the Astronomische Gesellschaft Catalogue. Lund Meddelande, Ser. 2, No. 65, contains a discussion of the proper motions of the stars in this zone by W. Gyllenberg. This list, which is the second one published, contains 277 stars, the determination of their proper motions being made by a graphical method. In order to test the validity of the method, the proper motions of ninety-three stars were also investigated by a rigorous least-square method. This comparison revealed the fact that the graphical method introduced a systematic error which makes the proper motions determined by it numerically too large. An explanation of the discordance, based on the theory of errors, was found, and formulæ deduced for correcting the graphical proper motions. The error increases with the size of the proper motion and can be rendered small by doing the graphical process twice; in the second graph the observations are corrected for the approximate proper motion found by the first graph. The faintest stars in the catalogue are of magnitude 9·4; several of these faint stars have considerable proper motion. Incidentally, it was noted that much trouble would be saved by excluding the catalogues of Lalande and Bessel; these aimed at quantity rather than quality, and many of the positions in them are inexact.

Work of the Government Chemist

DECREASES in the number of samples examined during the year ended March 31, 1932, by the Government Laboratory at Clement's Inn Passage, at the Custom House branch, and at seaport chemical stations are, as is stated in the report of the Government Chemist (H.M. Stationery Office, 1932. 9*d*. net), a sign of the present state of industry generally. Nevertheless, the examination of nearly half a million samples, together with the research work continuously involved in the maintenance and increase of efficiency, form the substance of the report of a very active year's work.

The Government Laboratory, while providing various departments of the public service with analytical reports on samples submitted to it, and reporting on samples referred to it by magistrates under the Food and Drugs (Adulteration) Act, 1928, performs a considerable number of services of general interest and purely scientific value. Thus, sea-water samples are examined in connexion with a scheme of oceanographical research carried out by the Fisheries Department of the Ministry of Agriculture and Fisheries, and by the Fishery Board for Scotland, acting in concert with the International Council for the Exploration of the Sea. The objects of these investigations are to trace the influence of salinity on fish life, and to trace the movements of water, apart from tidal motion, from one part to another in the sea.

Attention has also been directed to the preservation of cinematograph films of national importance, and the development of such films is now being carried out under supervision and control. The Laboratory's advice was also sought with regard to the best method of preserving cinematograph films taken on the "Discovery" expedition. At the laboratory in the Geological Survey and Museum, complete analyses of fifteen rocks were made, and various other specimens were subjected to tests. Methods have been worked out in connexion with the analyses of igneous rocks, metamorphic rocks, and minerals, and the determination of alkalis in rocks has been studied with the view of increasing the accuracy of the results.

Reporting on the composition of imported cheese, the Government Chemist states that only 43 per cent of the samples had been prepared from whole milk, but remarks significantly: "As, however, there are no regulations relating to the marking of skimmed or partially-skimmed milk cheese, no exception could be taken to any of the importations." Similarly, most of the samples of cream contained only 19–35 per cent of fat, the group containing 45–55 per cent representing only 9 per cent of the total; but "since there is no standard for cream in this country, exception could not be taken to the samples in respect of low proportion of fat". Examples of investigations of industrial interest are quoted.

A sample of synthetic resin was examined for the Office of Works in respect of its suitability for varnishing pictures, but the material was rejected since it developed acidity with lapse of time. Various paints, oils, and thinners were investigated to discover the cause of the defective drying of paint applied to the walls of a building, and one of the fluids examined was found to contain nitrobenzene in quantity sufficient to inhibit the drying of the paint. An investigation for the Admiralty, at present in progress, is the search for a relation between the tendency of oilskins to become 'tacky' in humid climates and the nature and proportion of the driers present in the oil, and its treatment.

Many samples of cider were examined in connexion with a scheme for grading cider entitled to bear the National Mark; a commercial preparation recommended for preventing 'cider sickness' but not permitted for use in such cider was found to be a solution of phosphoric acid. During the year about 150 mgm. of partially purified radium was recovered from decayed luminous paint, and 242 milligrams of partially purified radium was converted into high-grade salt of 66 per cent purity.

For the Imperial War Museum ninety medals and plaques have been cleaned, restored, and lacquered for preservation, work which necessitated a preliminary investigation into the character of the corrosion product. The services of the Laboratory were also requisitioned in a number of cases of suspected fraudulent use of stamps and repayment claims.

Irish Woods and their Significance

THOSE who have endeavoured to study the past history of the forests of a country have quickly appreciated the great difficulties which present themselves. Assumed facts and widely held theories are discovered to be based on the slenderest evidence, and have afterwards been so often repeated in histories and so forth as to have become accepted as incontrovertible facts. Ireland presents a remarkable illustration. In the majority of histories dealing with Irish economics during the past two or three hundred years, the statement is either made or implied that the greater number of the native forests of the country were destroyed during the sixteenth and seventeenth centuries. The reasons assigned are usually the removal, by felling or burning, of the natural shelter of Irish rebels during the Elizabethan and Cromwellian wars, the smelting of iron by means of charcoal, the exportation of pipe staves, etc. In some cases even this assumed destruction is imputed to the mere presence of the English in the country, and it is suggested that the native Irish had a keen sense of forest preservation, whilst the various intruders were entirely devoid of this quality.

To the energy and enthusiasm of Mr. A. C. Forbes we owe the exposure of this myth. In "Some Legendary and Historical References to Irish Woods, and their Significance" (*Proc. Roy. Irish Acad.*, vol. 41, Sect. B, No. 3, Dublin, 1932) Mr. Forbes traces the past history of the forests of Ireland and has produced a treatise of considerable value, historical and economic, which it may be hoped will evoke similar essays for other countries.

The author took as his main study the writers of well-known histories, treatises and descriptions of the country on one hand, and State papers on the other. As an example of the former Mr. Forbes quotes the following extract from Lecky's "History of Ireland in the Eighteenth Century": "A serious and enduring change passed over the material aspect of the country in the forty years that followed the revolution (of 1640) from the rapid destruction of its forest trees. The history of this destruction is a curious and melancholy one. When the English first established themselves in Ireland, no country in Europe was more abundantly wooded." Lecky then quotes the various authorities upon whom he relied for making "this extraordinary statement" as Mr. Forbes terms it. It is impossible to follow the author through his review of these authorities but he conclusively shows the absence of all proof for the statements made. The references made in or to State papers and memoranda yield more satisfactory data, but Mr. Forbes says they must be read with caution.

Mr. Forbes summarises his conclusions as follows:

(1) No trustworthy account of Irish forests as a whole during the medieval period is in existence. The occupation of the country by the Normans and Tudors had no material effect upon the wooded condition of the country, although considerable quantities of timber were cut for pipe staves, and for conversion into charcoal during the latter period.

(2) The forest laws of the Normans were applicable to Ireland in the same way as in England, but there is no evidence that they were enforced except in one or two cases, which the author deals with at some length. The various references to "forest" in the State papers pertained to the unenclosed or unappropriated land of the country, which was regarded as the property of the Crown. This forest had no definite connexion with woods or timber. Many similar instances are to be found throughout the British Empire at the present day.

(3) The annals, legends, and other documents relating to the prehistoric period suggest that the condition of Ireland for an unknown period was that of a huge grazing ranch, over which trees were scattered more or less generally. More thickly wooded districts doubtless existed, but no clear indication of the extent can be discovered from the translations made in modern times.

(4) The Irish forest flora does not appear to have changed during the last thousand years. While the pine (*Pinus sylvestris*) may have survived until comparatively recent times, all the reliable evidence on this point is entirely negative in character.

(5) The native forests were gradually destroyed by grazing and fire, continuing over a very long period, and not by any large scale or deliberate acts of destruction.

On the subject of the composition of Irish woods, the legends and annals relating to the early Christian period throw a good deal of indirect light upon the species of trees which were in existence between the thirteenth and fourteenth centuries, when the majority of the legends were first inscribed or transmitted to parchment or paper. Topography forms a prominent feature of these old tales and poems and references are made to plains, woods, lakes and mountains which suggest a general landscape very similar to that existing to-day, while the frequent references to cattle show that flocks and herds formed the chief wealth of Ireland, as is the case to-day. In a tale entitled "The Death of Fergus", the scene of which is laid before the historic period, the following list of trees is given: ash, green oak (which may distinguish it from the bog oak so common throughout the country), aspen, rowan, alder, holly, blackthorn, whitethorn, briar, willow, apple, elder, birch and yew. Woodbine is referred to as "the Monarch of Inisfail's forests", but pine and elm are not mentioned. The list is almost identical with one which might be drawn up to-day in any piece of native scrub.

Perhaps one of the most interesting problems presented by the forest flora is the disappearance of the pine as an indigenous tree. This disappearance would appear to have taken place before the historic period. It constitutes the most plentiful species in bog remains all over the country. Mr. Forbes suggests that the causes may be the competition of oak and ash on the better classes of soils and the burning by graziers on the mountain slopes. In the absence of any proof to the contrary, the suggestion would appear to be the most likely one.

The Extra-Galactic Nebulæ

A DECISION has been reached by the Council of the Royal Astronomical Society that in view of the fact that the gold medallist for the year is so frequently the same person as the George Darwin lecturer, the latter may be expected to explain in his lecture the work for which the medal has been bestowed; and the president should be free to choose a subject of his own for his address at the annual meeting. The retiring president, Dr. H. Knox-Shaw, at this year's annual meeting held on February 10, chose a subject with which the medallist, Prof. Slipher, is closely connected, but on which many others have laboured in recent years, resulting in a great increase in our knowledge; this is the problem of the nature and motion of the extra-galactic nebulæ. Slipher was a pioneer in the study of their radial velocities; these proved to be large (the first forty gave an average of 620 km./sec.) and mainly outwards, though some of the nearer ones were approaching. The latter velocities were diminished on correcting for galactic rotation.

The address went on to describe the various types of nebulæ, including elliptical, spiral, barred-spiral, and irregular; the differences arise partly from different angles of projection, but chiefly from differences in the stage of development. The subject of their distance was then examined; the first reliable determination was that by Dr. Hubble from his detection of Cepheid variables in the nearer spirals; a distance of some 900,000 light-years was deduced for the great nebulæ in Andromeda and Triangulum. The measures were pushed some distance further by the magnitudes of the stars in the nebulæ; when this failed, estimates were made by the total light and angular diameter of the nebulæ. From these methods Dr. Hubble deduced − 13·8 as the average absolute magnitude of the nebulæ; Dr. Knox-Shaw suggested the value − 14·5.

Going on to consider the radial velocities, Dr. Knox-Shaw suggested that it was best to take these as a true Doppler effect in the absence of any other probable hypothesis; this was strengthened by the fact that the same radial velocity was indicated by lines in different parts of the spectrum.

A description followed of the special spectrograph by which Dr. Hubble has extended his study of radial velocities to the faintest and most distant nebulæ; this is done by diminishing the scale of the spectrum and giving prolonged exposures; recessions up to 19,000 km./sec. (equivalent to 200 angstroms for the *H* and *K* lines) have been found. The corresponding distance would be about 120 million light-years; estimates from different groups of nebulæ gave the mean recessional speed as lying between 590 and 400 km./sec. at a distance of one megaparsec. Dr. Knox-Shaw made an estimate of the average peculiar radial velocity of a nebula, including the dispersion in absolute magnitude; he found the value 140 km./sec. It is thus important for the nearer nebulæ, but a very small fraction of the whole for the distant ones.

In conclusion, Dr. Knox-Shaw said that the absolute magnitudes of the Cepheids, and all estimates of distance based upon them, are still subject to some revision. The original values were not corrected for the absorption of light in space; there is accumulating evidence that some correction is needed, but the exact amount is still uncertain. The galaxy appears to be of such a complex character that the absorption in different regions is probably different.

A comparison was made between the components of nebular clusters and isolated nebulæ; the former appear to be on the average fainter than the latter by amounts ranging from 0·5 to 0·9 mag. It will be seen that the address was not merely an account of the results obtained by others, but included personal discussion of the conclusions to be derived from them.

University and Educational Intelligence

Birmingham.—Dr. J. F. Brailsford has been appointed radiological demonstrator in anatomy and W. J. Rees temporary assistant lecturer in botany.

London.—The Leathersellers' Company has decided to make a grant to the University of £1,000 in the shape of annual payments extending over a series of years. This benefaction will be applied towards meeting the cost of the new Ceremonial Hall to be erected on the University's site in Bloomsbury.

The Pilgrim Trustees have decided to make a grant of £1,500, payable in three equal annual instalments, towards the cost of the preparation and the revision of existing material for the "Victoria County History". It will be recalled that in November of last year the University accepted an offer received from Mr. William Page, the sole proprietor and editor, to give to the University the copyright and material of the "History".

Reading.—The Council of the University has appointed Dr. R. H. Stoughton to be professor of horticulture. For two years Dr. Stoughton acted as mycologist to the Rubber Research Scheme of Ceylon, and for the past six years he has been a member of the research staff in the Department of Mycology at Rothamsted Experimental Station. The chair of horticulture at Reading has only recently been established and it is the first post of its kind in Great Britain. The training of students in horticulture has, however, been for many years a feature of university teaching at Reading and Dr. Stoughton will take over the whole charge of the Department of Horticulture. He will act also as director of the university Horticultural Station at Shinfield, where a garden of about 20 acres, including greenhouses and a well-stocked orchard, provides facilities for the instruction of students in the practice of gardening. The Station also affords opportunity for research in horticultural problems.

The Society for Cultural Relations with the U.S.S.R. has decided to arrange an education tour for the Easter vacation of 1933, the suggested date of departure being April 8. The tour will cover about 21 days, 6 days being spent in and around Leningrad, and 8 days in and around Moscow. All types of educational institutions, urban and rural, will be visited. Opportunities for making contact with Soviet educationists will be provided. A Russian-speaking English educationist will lead the party. The cost, which includes travel to and within the U.S.S.R., hotel charges, tips, visits to museums, etc., will be approximately £37. Further particulars can be obtained from the Secretary, S.C.R., 1 Montague Street, London, W.C.1.

Two Lady Tata research scholarships, of the value of £400 a year each, will be open for award in June, 1933, to men or women in the British Commonwealth, exclusive of India, for research work in the subject of blood diseases, with special reference to leucæmias. Each will be tenable for a year, from October 1, 1933, and renewable up to a normal maximum tenure of three years. The scholarships will ordinarily be awarded on a whole-time basis, but a candidate holding a part-time teaching post may be allowed to retain this if his duties will not prevent him from giving his chief interests and energies to his proposed research work. Applications should be sent, on or before April 15, to the Secretary, Dr. H. S. Patel, Lady Tata Memorial Trust, Capel House, 62 New Broad Street, London, E.C.2, from whom forms of application may be obtained.

Calendar of Nature Topics

Sowing Agricultural Seeds

The drills will soon be at work sowing spring corn. Broadcasting by hand, firmly associated in literature with the committing of seed to the ground, was universal until the sixteenth century and only slowly gave way to drill husbandry. It is now almost a lost art in Great Britain, and even when local circumstances make broadcasting necessary, it is usually done by machine. The forerunner of the modern seed drill was devised by Jethro Tull in 1701 and its introduction together with the principle of inter-row cultivation, which was part of Tull's system, represents one of the historical land-marks of agriculture.

With centuries of mechanical improvement it might have been expected that the present-day seed drills would be practically perfect. This is not the case. The ideal implement, sturdy enough to stand the rough usage of the farm, yet capable of distributing seed at a uniform and accurately adjustable rate from each of its many coulters, has not yet been constructed. Recent detailed studies of the distribution of the plant population in fields of cereals and roots have revealed a startling variation in density which is associated with equally marked differences in yield. Irregular sowing was found to be one of the main causes of this. There is no doubt that more uniform spacing of the seed in the rows would lead to higher yields, and when a demand for more accurate seed drills makes itself felt improved designs will be forthcoming.

Where do Flies go in Winter?

Gilbert White noticed that "in the decline of the year, when the mornings and evenings become chilly, many species of flies (*Musca*) retire into houses, and swarm in the windows", but he thought that they died there. There is, however, sometimes an interesting sequel to the autumn swarms of flies in houses. Generally in February, occasionally in January and March, householders in various parts of the country have complained about the appearance of swarms of flies. One such case was investigated in Edinburgh by Prof. J. H. Ashworth on February 22, 1916 (*Scot. Nat.*, 1916, p. 81). Swarms were then present in four rooms of a house, where for sixteen years they had congregated annually in September or October. Generally they disappeared before the end of November, but sometimes they persisted through the winter. The evidence suggests, however, that it was not a simple case of continuous persistence; for although Ashworth almost cleared one of the rooms on February 22, he found on March 7 that a considerable number of flies had again collected, as if they had emerged from crevices in which they had been hibernating. Only rooms with a southern aspect were affected, and at its largest the swarm in one room was reported to cover the bay-window and to have formed in addition a mass on the ceiling which resembled a thick coil of black rope some three inches in thickness.

Evidence of hibernation was more direct in the swarm which Major T. K. Gaskell observed at Lahill, Largo, Fife, in February 1915, for there he actually saw the small flies emerging from a crack behind the mantelpiece in his bedroom, which faced west. Probably their winter rest had been disturbed by the fire lit in the guest chamber. He collected in that, and the following year, some 700 individuals. Hever in Kent, Swindon in Gloucestershire, and other places have contributed all in one winter to the records of swarms of flies in houses, and show that the event is of wide occurrence.

Composition of Fly Swarms in Dwelling Houses

It is a remarkable fact that none of the swarms examined contained a single example of the common house-fly (*Musca domestica*). The swarms were really made up of a small anthomyid dipteron, *Limnophora septemnotata*, which was accompanied by odd individuals of muscid diptera, such as *Pyrellia eriophthalma*, *Muscina stabulans* and *Pollenia rudis*. A second interesting fact was that, in the two swarms fully analysed (Edinburgh and Largo), P. H. Grimshaw found all the specimens of *Limnophora* to be female. Ashworth's examination of ten specimens taken at random showed that all were impregnated, the receptacula seminis being crammed with active spermatozoa, presumably received in the previous autumn from males which had since died. The females alone carried on the race over winter, each survivor being ready, on the return of suitable conditions, to emerge from its winter quarters, feed, mature its ovaries, and produce eggs to be fertilised by autumn spermatozoa.

A third point of interest was that, as a rule, the dipterous swarms were accompanied by small hymenopterous parasites, the chalcid *Stenomalus muscarum*, the females of which are said to lay their eggs upon the larvæ of muscid flies. Moreover, all the hibernating chalcids of this species which Dr. James Waterston examined were females, and in describing the occurrence (*Scot. Nat.*, p. 140, 1916) he asked the pertinent question: "Is the occurrence of this Chalcid with the Diptera a fortuitous association to be explained simply on the ground that different species have selected the same winter quarters, or have we here an adaptation of habit on the part of the Chalcid enabling the parasite to oviposit most advantageously in the spring?"

Heredity and Hibernation in Insects

In his invaluable work on "Insects and Climate", B. P. Uvarov has summarised records regarding the hibernation of insects which suggest the existence in many species of a fixed seasonal life-cycle which may be disturbed by unusual temperature conditions but cannot readily be annulled by them (*Trans. Ent. Soc. Lond.*, 79, 105; 1931). Hibernation has become a habit which is fixed and is transferred with other heritable properties from one generation to the next. How has this habit become engrained in the course of evolution? It has been suggested that individuals in which the life-cycle was not properly adjusted to the conditions of environment would suffer and finally be eliminated, leaving only the well-adjusted to survive; in other words, that natural selection has been responsible.

Uvarov, however, refers to experiments carried out by Pictet on the caterpillars of the oak eggar moth which are very suggestive. His summary is as follows:—"Pictet (1913) himself bred caterpillars of *Lasiocampa quercus*, L., at 22° for six successive generations, with the result that, while in the first generation all caterpillars hibernated normally when the time arrived, in the fifth generation 52 per cent of the caterpillars were only inactive for one month, and 18·7 per cent developed without hibernation at all, and in the sixth generation practically all the caterpillars developed without hibernating. Under these conditions the adults can be obtained at almost any season, instead of in July–August, when they emerge normally, although about 50 per cent still tended to emerge at the usual time, owing to an adjustment in the length of the pupal period. Pictet used the results of his interesting experiment as an argument that the annual life-cycle is constant and hereditary, its origin being due to natural selection. They serve, however, to support even better the idea that the life cycle of a species can be directly influenced by the seasonal climatic cycle. Indeed, since only six generations were necessary to produce a substantial change in the life-cycle, in adjustment to new conditions, it is reasonable to suggest that a climatic cycle acting on a species for countless generations may make that species perfectly adjusted to it without the aid of natural selection." We have not seen Pictet's paper (*Bull. Soc. Lépidopt. Geneve*, vol. 2, pp. 179–206; 1913) and do not know whether the possibility of mortality in the different generations of his caterpillars may affect the argument, but progressive adaptation in generation after generation suggests something very like the inheritance of an acquired modification in the habit of hibernation.

Societies and Academies

London

Royal Society, Feb. 9. W. S. Stiles and B. H. Crawford: The luminous efficiency of rays entering the eye pupil at different points. It is commonly assumed that the apparent brightness of an object is proportional to the pupil area. This assumption is shown to be invalid, and measurements are described which give the relative luminous efficiencies of rays entering the pupil at different points. From these data, the overall luminous efficiencies of eye pupils of different diameters are computed, and checked by direct measurement. The effect may originate in the eye media or in the retina itself. R. J. Ludford: Differences in the growth of transplantable tumours in plasma and serum culture media. The malignant cells in tissue cultures of tumours can be distinguished from the non-malignant cells by the addition of trypan blue to the cultures, since the former do not segregate the dye like the latter. The two types of cells are further distinguishable by other characteristics. In plasma cultures, both malignant and non-malignant cells migrate from the explants. In serum cultures only non-malignant cells wander out from the explants. In serum cultures the explants of carcinomata soon become rounded and the explants of sarcomata tend quickly to disintegrate. The outgrowth of non-malignant cells in serum cultures is usually greatest when tumours are explanted at a time when they are not growing at their best *in vivo*. It is suggested that the different behaviour of malignant cells in plasma, and in serum, is the result of an alteration in their plasma membrane such that they are unable to adhere to glass, though able to use the fibrin network of a plasma clot as a support for their movement.

Mineralogical Society, Jan. 26. L. J. Spencer: Meteoric irons and silica-glass from the meteorite craters of Henbury (Central Australia) and Wabar (Arabia). The meteoric iron from these two localities is of exactly the same type, namely, a medium octahedrite containing 7·3 per cent of nickel. At Wabar a 25 lb. mass and a few small fragments of iron were collected; but at Henbury thousands of masses of iron are scattered around the craters. In the smallest (10 yd.) crater a group of four masses (440 lb.) was excavated at a depth of 7 ft. Many of the smaller pieces scattered around the craters are curiously twisted and bent, suggesting that they were torn in a plastic condition from the main masses by the force of the explosions. Further, they show a partial obliteration of the lamellar structure with granulation of the kamacite, indicating that they reached a temperature of 850° C. The pieces of iron show different types of pitting resulting from sub-aerial and underground weathering, and they are all weathered remnants of larger masses, each consisting of a single crystal. (See also Nature, 131, 117, Jan. 28; 172, Feb. 4, 1933.) A. Brammall and S. Bracewell: Garnet in the Dartmoor granite: its petrogenetic significance. Seventeen occurrences prove to be manganiferous almandines containing 3–22 per cent of MnO. Two or more varieties may occur in a single hand-specimen of the granite. The more manganiferous varieties (7 per cent MnO) are restricted to the tor-horizons; the less manganiferous varieties occur (*a*) below these horizons, (*b*) in shale-contaminated facies of the granite, and (*c*) in xenolithic hornfelsed shale. Basic igneous inclusions are barren of garnet, and grossularite, *not* almandine, occurs in contact-altered spilites. The mineral is attributed to contamination of the granite by country-rock—probably deep-seated shales. Ten Lake District occurrences show a similar variation (1·3 per cent–7·3 per cent MnO). F. A. Bannister: The identity of mottramite and psittacinite with cupriferous descloizite (cuprodescloizite); (with chemical analyses by M. H. Hey). Oscillation, Laue and rotation photographs show that descloizite has an orthorhombic unit-cell with edges $a = 6{\cdot}05$, $b = 9{\cdot}39$, $c = 7{\cdot}56$ A. and space-group Q_h^{16}. The unit cell contains $4PbZn(VO_4)(OH)$. Powder photographs of descloizite, cuprodescloizite, mottramite, and psittacinite from the type localities are identical with each other. New chemical analyses and determinations of the water content at various temperatures together with the X-ray work show that all these minerals may be represented by the general formula $Pb(Cu, Zn)(VO_4)(OH)$. The water of constitution is not evolved until a dull red-heat. Thin incrustations of minute black crystals on sandstone from Harmer Hill, Clive, near Shrewsbury, collected by Mr. Arthur Russell, are identical with mottramite from Mottram St. Andrew, Cheshire (H. E. Roscoe, 1876), that is, cuprodescloizite carrying little or no zinc.

Edinburgh

Royal Society, Jan. 9. J. G. Gray: Self-erecting gyrostats. The lecture was illustrated by experiments carried out with a large series of new gyrostatic tops and combinations invented by Prof. Gray and constructed with a view of demonstrating and explaining technique which he has developed for use in the practical applications of gyrostatics, notably in applications to the navigation of marine and aerial craft, and for use in the construction of stabilisers for use in such craft. J. E. Mackenzie and H. W. Melville: Experimental demonstrations of the measurement of the diffusion coefficients of bromine–hydrogen and bromine–carbon dioxide. This experiment is likened to a horse race in which all the horses have the same speed and colour (say chestnut), but each horse runs in a track differing in difficulty from the track of every other horse. Bromine molecules (chestnut horses) diffuse through tubes filled with hydrogen or carbon dioxide or other gas, and the distances covered by the bromine in each tube are measured visually at intervals of time. (See Nature, 130, 322, Aug. 27, 1932.) H. S. Ruse: The measurement of spatial distance in a curved space-time. A definition of spatial distance in a general space-time obtained in an earlier communication by a purely mathematical argument is in accordance with the concept of 'distance' fundamental in relativity, namely, that determined by the use of rigid measuring rods.

Paris

Academy of Sciences, Jan. 3 (196, pp. 1–71). H. Douvillé, M. Solignac and E. Berkaloff: The discovery of the marine Permian at Djebel Tébaga (extreme South Tunisia). St. Golab: The conformal representation of Finsler space on Euclidian space. Elie Cartan: Remarks on the preceding communication. S. Finikoff: Pairs of surfaces the lines of curvature of which correspond, the corresponding tangents cutting. **ARNAUD DENJOY**: The polygons of approximation of a rectifiable curve. **S. MAZUR** and **W. ORLICZ**: Linear methods of summation. **N. BOTEA**: Some partial differential equations. **J. DIEUDONNÉ**: Radii of *étoilement* and convexity of certain functions. **TCHANG TE-LOU**: The electrical and thermomechanical phenomena during ignition and combustion in an internal combustion motor. **DELFOSSE** and **SWYNGEDAUW**: Certain conditions of working of ball bearings. **F. HOLWECK**: Study of a sensitive elastic pendulum. Contribution to the establishment of a French gravimetric network. **P. LEJAY**: The establishment of the gravimetric map of the north of France. **S. SOBOLEFF**: The equation of the wave on the logarithmic surface of Riemann. **FRANCOIS CANAC**: Study of the mode of corrosion and of the susceptibility to corrosion of metals by the diffusion of light. **R. DE FLEURY** and **A. CAILLON**: The composition and mode of use of a flux assuring the protection of the metal, its refining and the elimination of chlorides in casting magnesium. **E. AUBERT DE LA RUE**: Some mineral deposits of the Saint-Pierre and Miquelon Islands. **H. ARSANDAUX**: The origin of the secondary dome of Mt. Pelée. **L. GRIGORAKI**: A new medium for preserving dermatophytes (pleomorphism, acquired characters, tissue specificity). **F. VLÈS**: Researches on the intervention of electrical conditions in the growth of children. **CH. SANNIÉ** and **R. TRUHAUT**: The mercury-reducing power of certain aminoacids. **JAMES BASSET** and **M. A. MACHEBŒUF**: Studies on the biological effects of ultra-pressures. Studies on immunity: the influence of very high pressures on certain antigens and antibodies. The toxin of tetanus loses its activity after exposure to a pressure of 13,500 atmospheres, but then possesses no immunising activity. It is not an anatoxin. At this high pressure antitetanus serum is precipitated as a jelly but the antitoxic power is not wholly destroyed. **A. LACASSAGNE**: Malignant tumours produced in the rabbit by the irradiation of inflammatory foci.

VIENNA

Academy of Sciences, Oct. 20. **JOSEF KISSER** and **H. SCHMID**: Investigations on the permeability of the seed coats of *Pisum* and *Triticum* to water and on the suction forces of the seeds. **J. KISSER** and **J. SCHUBERT**: The influence of treatment of seeds with chemical stimulants on the cell growth of the rootlets. When seeds of *Pisum* and *Triticum* are treated with alcohol, manganese sulphate or chloride, magnesium chloride or zinc sulphate in suitable concentrations and for suitable periods, considerable increase in root growth is produced. **J. KISSER** and **R. FURTAUER**: The influence of certain chemical agents on the carbon dioxide output of germinating seeds of *Pisum sativum* and *Triticum vulgare* under optimum germination conditions. In certain concentrations, alcohol enhances the production of carbon dioxide by *Pisum* seeds, but it is not certain if this effect is a true stimulative action or if it is due to the use of the alcohol as a nutrient. According to their concentration, magnesium chloride and manganese sulphate and chloride may either increase or diminish the output of carbon dioxide; the effect is influenced also by the presence or absence of the husk and by the phase of the germination when the salt solution is applied. **J. KISSER** and **FR. ZEISEL**: Physiological investigations on interrupted nutation. **J. KISSER** and **R. PIEPE**: Further investigations on the material foundations of tropistic curvature. **J. KISSER** and **I. BEER**: The chemotropic sensitivity of dicotyledonous seedlings. **ANTON KAILAN** and **OTTO STUBER**: The velocity of catalysed hydrogenations. The hydrogenation of oleic acid in presence of nickel and other catalysts supported on different carriers has been studied. **FERDINAND STEINHAUSER**: Temperature relations in Vienna during different seasons and at different times of the day (1931–1932). **JOSEF SCHINTLMEISTER**: The ionisation of H-rays in different gases. From the results as yet obtained, it must be concluded that this ionisation exhibits no abnormalities. **ULRICH KHUNER**: Experiments with space-acoustic models, and measurement of acoustic absorption coefficients. **K. F. WENCKEBACH**: The mechanism of sudden heart-failure in cases of beriberi. Observations made in the Dutch East Indies and Singapore indicate that the marked broadening of the right heart and the danger of speedy heart-failure accompanying beriberi depend on two factors, one cardiac and the other peripheral. These factors act from the beginning of the disease and are produced by the causes of the disease, but appear to differ essentially. **EMIL ABEL** and **HERMANN SCHMID**: Flow kinetics: model of photolysis. Certain special cases of flow kinetics, serving as a model of photolysis, are considered, and a kinetic interpretation of Beer's law of absorption is given. **FRANZ HOLZL** and **WALTHER STOCKMAIR**: The complex anion of Buff's compound and of Bunsen's salt. These compounds contain a common anion and are represented by the formulæ $(ROH.H)_4[Fe(CN)_4Cl_2]$ and $(NH_4)_4[Fe(CN)_4Cl_2]$ respectively. **MILOS MLADENOVIC**: Elemic acid from Manilian elemi resin (6): A new oxidation product of α-elemolic acid. **KONRAD FUNKE**: Perylene and its derivatives (37): Oxidation of dinitro- and diaminoperylene. **HANS KOPPER** and **ALFRED PONGRATZ**: The Raman effect (24): The Raman spectrum of organic substances (molecules with cumulated double linking). The vibration spectrum of allene corresponds exactly with that of a symmetrical linear molecule with a C : C double bond. With allene derivatives, cleavage of the principal frequency $\Delta\nu = 1074$ cm.$^{-1}$ occurs, and for the isocyanate group the frequency $\Delta\nu = 1420$ cm.$^{-1}$ is characteristic. **R. KREMANN**, **FRANZ GRIENGL** and **HELMUT SCHREINER**: The viscosity of partially miscible liquid mixtures (1): The system phenol-water. **ROBERT KREMANN**, **ESTER INGE SCHWARZ**, and **SIDY LE BEAU**: Experiments on the electrolysis of fused iron-aluminium alloys and the degree of solubility of iron in molten aluminium at different temperatures. **R. KREMANN** and **LUDWIG LAMMERMAYER**: The electrolysis of aluminium alloys containing iron as a model of the electrolytic purification of molten aluminium from iron. During this electrolysis, the iron migrates towards the cathode, but this effect diminishes as the aluminium content increases and is very slight for nearly pure aluminium. It is, therefore, improbable that aluminium can be freed from iron electrolytically. **LUDWIG LAMMERMAYER**: Electrolysis of a fused beryllium-copper alloy containing 10 per cent of beryllium. **ARTHUR PONGRATZ**, **FRANZ GRIENGL**, and **J. CECELSKY**: Perylene and its derivatives (38): Heats of combustion. **KARL LINSBAUER**: Action of calcium and potassium solutions on the protoplasm of *Chara*. **LUDWIG LAMMERMAYER**: Plants on the basalts of eastern Styria. **FRIEDRICH MORTON**: Results of a botanical expedition to Abyssinia, Egypt, and the Quarnero district (1931–1932). **RUDOLF WAGNER**: The existence of Δ-Sichel sympodia.

Forthcoming Events

Saturday, Feb. 18

ROYAL INSTITUTION, at 3.—Lord Rutherford: "Detection and Production of Swift Particles" (succeeding lectures on Feb. 25 and March 4 and 11).

Monday, Feb. 20

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—J. Vincent: "The Namuli Mountains, Portuguese East Africa".

Tuesday, Feb. 21

CHADWICK PUBLIC LECTURE, at 5.15—(in the Lecture Hall of the Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, W.1).—Dr. M. B. Ray: "The Hippocratic Tradition".

BRITISH MEDICAL ASSOCIATION, at 8—(Sir Charles Hastings Lecture at the Association's House, Tavistock Square, W.C.1).—Sir Henry Gauvain: "Sun, Air, and Sea Bathing in Health and Disease".

Wednesday, Feb. 22

ROYAL SOCIETY OF ARTS, at 8—(Trueman Wood Lecture).—Sir William B. Hardy: "Industrial Research with Biological Material".

Thursday, Feb. 23

BEDFORD COLLEGE, LONDON, at 5.15.—"Contemporary Developments in Science." Prof. T. M. Lowry: "Chemistry in Three Dimensions".

Friday, Feb. 24

ASSOCIATION OF ECONOMIC BIOLOGISTS, at 2.30—(in the Botany Lecture Theatre, Imperial College of Science and Technology).—Annual Business Meeting.

INSTITUTION OF PROFESSIONAL CIVIL SERVANTS, at 5.30—(in the Lecture Hall of the Royal Society of Arts).—O. G. S. Crawford: "Air Photography and Archæology".

ROYAL INSTITUTION, at 9.—Prof W. A. Bone: "The Photographic Analysis of Explosion Flames".

ELECTRICAL ASSOCIATION FOR WOMEN, Feb. 22–24.—South-Western Conference to be held at Torquay.

ASSOCIATION OF TECHNICAL INSTITUTIONS, Feb. 24–25.—Annual Meeting. Feb. 24.—Sir Hugo Hirst: Presidential Address. Also, discussion on "Policy in Technical Education" to be opened by Dr. Percival Sharp.

The Ancient Monuments of England

POSSIBLY few of the public who visit our ruined castles, abbeys and other historic sites are conscious of the extent of their indebtedness for their æsthetic enjoyment or the satisfaction of their intellectual interest to the activities of the Office of Works in the exercise of the powers conferred upon it under the Ancient Monuments Acts. The Friday evening discourse on "The Ancient Monuments of England" delivered by Sir Charles Peers, the Inspector of Ancient Monuments, at the Royal Institution on January 27, served a double purpose by demonstrating the various forms of activity of the Office of Works in carrying out this branch of its duties, and in reminding his hearers why these duties should have come to be accepted as the responsibility of a government department functioning at the charge of the State.

The sense of national responsibility in the matter of the preservation of ancient monuments and buildings, which afford concrete evidence of the life and history of Britain in the past, has been a plant of slow growth. As Sir Charles Peers pointed out in opening his address, the term 'ancient monument' has been in use no more than fifty years ; nor does it even now apply to every monument of antiquity. Until recent legislation, it covered only certain restricted classes of prehistoric remains ; and it does not apply to any church, inhabited house, or to Crown property. Although Sir Charles did not dwell on this aspect of his subject, the dangers are patent.

Any building or structure which falls within these latter categories, whatever its historic interest or æsthetic value, is at the mercy of any craze for 'improvement' or restoration, however well- or ill-instructed, or even, in the instance of the private owner, of desire for pecuniary gain. In the not very remote past, priceless panellings and carvings in wood and stone have been torn from their settings and sent to America ; and only a year or two ago the historic palace of Queen Elizabeth at Enfield was demolished, although a public-spirited purchaser was ready to forgo a handsome profit, had a public body been prepared to accept his offer to sell at a comparatively low price. An object-lesson of the enforced impotence of the Office of Works is afforded by the reply of Mr. W. J. Ormsby-Gore, as First Commissioner of Works, when asked recently in Parliament if his Department would not intervene to secure the preservation of the historic buildings of the Adelphi on the Thames Embankment. Archæologists who are more immediately concerned with the preservation for science of the material bearing on the period before written records, have shown repeatedly that they would welcome a greater measure of control over the exploitation of privately owned sites of archæological interest.

It must be admitted that under recent legislation great advance has been made, especially in the field of prehistoric and early historic times. The recent additions to the list of scheduled 'monuments' mark a greatly extended range for the operation of the Acts. Individual acts of vandalism, it may be assumed, will always be with us; but public opinion may now, perhaps, be credited with being so far educated as to deprecate, and even to do its best to prevent, anything like the wholesale destruction which threatened the stone monuments of Dartmoor or the neglect which allowed a monument like Stonehenge to fall into a deplorable condition a generation ago. It is rather the less conspicuous and spectacular sites which call for 'protection'.

Sir Charles Peers spoke of the distinguishing marks which primitive man by the use of his hands has set on natural objects, marks which set him apart from all other living things. These are documents beyond price for the study of the early history of man. While, as Sir Charles said, the work of man can never be obliterated by natural forces, it is equally true that it can be defaced and destroyed by man himself. However meagre, scattered, or insignificant, such evidences of man's early progress should be preserved from the destructive activities of both ignorance and deliberate vandalism.

Speaking more particularly of prehistoric antiquities, this desire to preserve even the least vestige that has survived from the past arises from no spirit of mere antiquarianism. Those who for many years pressed for the enlargement of the powers conferred on public authority under the Ancient Monuments Acts had more in mind than preservation for its own sake. Their object, from the point of view of archæological science, was immediately practical—the preservation of the data with which the archæologist must work. If we are able to present a connected story of the past in Britain from the time of our later stone age, say, 2300–2000 B.C., as Sir Charles Peers said, even though we cannot lay claim to a civilisation comparable to the venerable culture of Mesopotamia or ancient Egypt, it is due to the synthetic studies of those who by patient plotting of scattered details on distribution maps have elicited conclusions out of all proportion to the apparent significance of any one piece of evidence taken in isolation. Yet in many instances such evidence has survived by happy chance rather than of design.

As an example of what has been achieved, Sir Charles surveyed present archæological theory of the early peopling of the British Isles by the megalithic peoples and the beaker-folk; and in another connexion he spoke of the results of the series of excavations which in recent years have been carried out on the hill-top camps in different parts of the country. He might also have referred to the enlargement of our knowledge of the mode of life of prehistoric peoples which has come from single sites where there was little to show the casual observer before investigation, such, for example, as the home of the flint-miners of Blackpatch in Sussex and, had Scotland come within his purview, the bronze age village at Skara Brae, explored with the co-operation of the Office of Works under the direction of Prof. V. Gordon Childe, the most remarkable and illuminating habitation site of that period north of the Alps.

In emphasising the evidential value of material, much of which may be comparatively unimpressive, and the need for its preservation, it must be remembered that there is another side to the question. We owe a duty to posterity. There are at least two reasons why we should hand on to our descendants these evidences of antiquity in a state of preservation at least not less secure than we have received them. On one hand, they are the possessions not of a day, but for all time. On the other hand, if there is one lesson to be learned from the progress in archæological studies during the last ten or fifteen years, it is that both method and theory in archæology are being developed with great rapidity. Hence it behoves us to preserve untouched at least a part of that material to serve the needs of a generation better instructed than our own. On more than one occasion recently, directors of excavations have recorded that they have left part of a site untouched for future investigators. This might well be made a condition of permission to excavate or of the co-operation of the Office of Works in the examination of a site.

In looking to the rights of future generations, it is inevitable that the question of repair and restoration should arise—a question of considerable difficulty in which, however, no better guide could be sought than Sir Charles Peers himself. Happily for the prehistorian, this is a question of less complexity in dealing with a prehistoric monument than it is for those who have the charge of early historic or medieval buildings. Repair, in the view held by Sir Charles Peers, should be reduced to a minimum, and considered as auxiliary to archæological investigation. As an illustration, he referred to the recent work carried out under the supervision of the Society of Antiquaries at Stonehenge where, after this monument had been presented to the nation in 1919, steps were taken to prevent the fall of unstable uprights, and much valuable information bearing on the methods employed by the builders of the monument was obtained. Under present legislation, the future of our prehistoric monuments should be secure. They need for the most part nothing more than that they should be left undisturbed, pending the time when their careful examination in the interests of scientific archæology may be thought desirable.

The difficult question of repair and maintenance was more nearly germane to the latter part of Sir Charles's lecture, in which he dealt with the more representative monuments of the early historic periods, Roman, Saxon, Dane and Norman. Here the question is not one of sites but of buildings, and he showed his audience in some detail the work that has been carried out with the co-operation of the Office of Works on such historic monuments as the coast-fortress of Anderida, now Pevensey, Portchester Castle, Whitby, Rievaulx and Byland, where much has been learned of medieval life and technical achievement from what in some instances, before operations began, had been no more than grass-covered hillocks.

Enough has been said, it is hoped, to indicate why the preservation of ancient monuments should be regarded as a national duty under the supervision of a public department, as is the safe custody of written records. The latter, however, stand in a different category. They can be kept under conditions which ensure their safety, so far as that is humanly possible, and they are accessible to the public only under proper supervision. Ancient monuments, we may say in a large number of instances, cannot be kept under 'lock and key'. Further, they are open to the vicissitudes of the weather and other causes of decay; hence the appeals to the purse of the public, when some building of historic interest and importance is in danger, as happens, unfortunately, all too frequently. The Ancient Monuments Acts may ensure the protection of a site or structure in a technical sense by including it in the schedules to the Acts. They cannot thereby make provision for its maintenance, and this may involve a heavy sum. The best protection for an ancient monument is a public which has been trained from school age to recognise and reverence with understanding the relics of its past; and the maintenance of a monument which is a national treasure should be a public charge.

Diamonds

The Genesis of the Diamond. By Alpheus F. Williams. Vol. 1. Pp. xv+352+vi+89 plates. Vol. 2. Pp. xii+353–636+iv+plates 90–221. (London: Ernest Benn, Ltd., 1932.) 84*s*. net.

THE author of this monumental work on the diamond has supreme claim to authority on the subject, having been connected with the diamond industry for more than thirty years, latterly as general manager of De Beers Consolidated Mines, Limited, and consulting engineer to the Jagersfontein and Koffyfontein mines, and in former years as assistant to his predecessor in that post, his father, Dr. Gardner F. Williams, whose book, "The Diamond Mines of South Africa", published in 1902, gave the first authentic account of the rise and development of the diamond mines of South Africa. The present book is not confined to its titular subject, but gives also a very readable account, fully illustrated, of the present-day practice of diamond mining and recovery, as adopted by the De Beers Company at Kimberley and elsewhere, as well as a chapter on the alluvial diggings in the diamond-bearing gravels of South Africa.

So long ago as 1899, Mr. Alpheus Williams had started to record data bearing on the origin of the kimberlite pipes (the 'blue ground') and fissures, and the nature and genesis of the kimberlite itself. He also commenced making a collection of diamonds, the natural uncut crystals, with the object of determining the conditions under which the diamond crystal grows. Those who, in 1929, had the privilege of seeing this collection, and that of the crystal-inclusions other than diamond in the kimberlite, as well as the wonderful series of photographs showing the surface structure of diamond faces and the internal markings and enclosures, and photomicrographs of rock and crystal sections, will best appreciate the immense value of this unique private museum—for such it amounts to. All must rejoice that wishes, then so fervently expressed for publication of a book dealing with it, shall have come to fruition.

One of the most interesting and successful pictures in the book is one in colour of the collection of uncut diamonds, natural size. There are also coloured reproductions of the more important of the 500 photomicrographs of rock-sections, most of the actual sections having been one and a half inches in diameter, in order the better to display the complete structure. Very valuable also are the many large-size photographs exhibiting practically every variety of diamond twinning, including cyclical and polysynthetic twins, as well as the star shapes and other better-known types. There are also projection-growth and cavity-form photographs, and others illustrating the glide planes in diamond.

Mr. Williams's mature view is that the kimberlite magma was of very deep-seated origin, genetically related to the magma which produced the ultra-basic rocks; and that, after the solidification of these latter rocks, they were fractured and at the time of the rise of the kimberlite magma fragments of them were carried up and eventually became impounded in the kimberlite at the time of its solidification. As regards the shape of the pipes, filled with kimberlite, the statement that they are generally round or elliptical in section, and resemble circular vents, is incorrect, this only applying to the shape near the surface; at greater depths they become more and more simple fissures. Some very convincing diagrammatic sections are given of the Kimberley pipe at different depths. The pipes are shown not to be volcanic craters or necks in the ordinary sense of the terms, but simply enlargements of a single fissure or of a junction of two fissures. Mr. Williams has found no evidence in support of the view so often expressed that violent explosive action had occurred during the rise of the molten magma which is now found filling the pipes and fissures. The explosive action occurred when the fissure was formed, before the rise of the kimberlite magma. Probably, owing to more rapid cooling, the magma solidified first in the fissures, while the contents of the enlargements, the pipes, were still more or less plastic, so that very little intermixture of lower and upper magmas could have occurred. Hence fissure kimberlite is generally of lower diamond content than pipe kimberlite.

The author further explains that crystallisation of carbon into diamond started on a limited scale in the very early stages of the solidification of the original magma into the plutonic rocks found now as cognate inclusions in kimberlite. That the carbon had already crystallised at this stage is proved by the fact that some of these cognate inclusions carry diamond. The condition most favourable for the crystallisation of the diamond would probably follow some process whereby the carbon content of the magma would be concentrated. This would occur in the first instance during the period of the crystallisation and formation of the peridotite and pyroxene rocks, and a further concentration would occur when the magma began to rise. The conditions for the crystallisation of carbon into diamond would therefore be more favourable in the magma left behind. It was in this residual magma, before its ascent in the fissures and pipes, that the crystallisation of diamond was greatest. This richer portion in turn rose and intermixed with semi-plastic magma already filling the pipe.

As to the genesis of the diamond itself, it is now generally accepted that the diamond was not crystallised in situ. The author shows that kimberlite is essentially a mica-olivine rock containing many transported crystals of olivine, enstatite, garnet, diopside, phlogopite, and so on, as well as clusters of these minerals, and as the diamond was one of the first minerals to crystallise it must therefore also be a transported mineral. The diamond has already been shown to have crystallised out of the original magma before eruption, and in some cases before the solidification of the peridotite and pyroxene rocks, for these rocks occasionally carry diamonds, as already mentioned. The bulk of the diamonds, however, must have crystallised out of the magma which remained after the formation of the peridotite and pyroxene rocks. At the same time, there crystallised magnetite, graphite, ilmenite, garnet, diopside, olivine, phlogopite, and zircon.

In spite of the numerous attempts to reproduce diamonds artificially, the author does not believe that anyone has yet imitated the process of Nature. Enormous sums of money have been expended in the quest, but grave doubts are felt as to the justification of claims that experiments, however costly, have resulted in the creation of diamonds.

Sir William Crookes in 1897 at the Royal Institution, and again in 1905 at Kimberley, expressed the view that the diamond problem was no longer insolvable, in view of the development of the electric furnace. Yet to-day, twenty-eight years later, we appear to be in the same position, with no practical advance effected. In 1924 Sir Charles Parsons said that he had been trying to make diamonds for twenty years, and had spent twenty thousand pounds on his experiments, but had come to the conclusion that nobody had ever made diamonds, the claims of Prof. Moissan and Sir William Crookes having been mistaken.

As regards the crystal form and structure of the diamond, there can no longer be any doubt that it belongs to the highest, holohedral, class 32 of the cubic system. The frequent suggestions for a lower class of the system ('hemihedrism') are really due to the fact that the diamond in habit assumes more 'forms' of the same system than any other crystallised substance, garnet most nearly approaching it in this respect. The different conditions under which the crystals have separated from the magma are probably responsible for this, the influence of surface tension in the liquid from which they separated being very pronounced. For the formation of a crystal face is dependent on two forces, the interatomic force striving to produce characteristic planes at right angles (normal) to the attractive force, and the force of surface tension counteracting this and striving to produce sphericity.

Temperature, fluidity, sizes of atoms, all are factors in determining the resultant of these opposing forces. The striving for sphericity, while at the same time the crystallographic laws are being obeyed, is clearly shown by the diamond, which so often takes its full 'form', that of the hexakis-octahedron, the 48-faced solid which is so nearly spherical. When this force is less effective, the tetrakis-octahedron is produced instead, hence the claims for hemihedrism. Fortunately, X-ray analysis has decided that the diamond is truly holohedral, a conclusion further confirmed by piezo-electric experiments at Cambridge by Dr. Wooster, with diamonds provided by the author. The whole of Mr. Williams's own work and investigations in so many directions are in agreement with this conclusion.

A most fascinating chapter, illustrated by exquisite photographs, follows on the growth of the diamond, which must be read to be appreciated. A pathetic statement occurs here, showing how commercialism so often impedes instead of helping scientific work. It reads: "An interesting feature may appear on the face of a diamond worth ten thousand pounds, the only record of which will be the photograph, because once the diamond enters the trade it is lost for ever from a scientific point of view." Hence, the world of knowledge is deeply indebted to the author of this delightful and valuable book for having secured these photographic records at the one and only psychological moment possible in each case, on the passage of these gems, Nature's loveliest of all crystals, from the 'pulsator' and sorting room of De Beers at Kimberley to the diamond cutter's destructive workshop. A. E. H. TUTTON.

Animal Myths

Animal Lore in English Literature. By Dr. P. Ansell Robin. Pp. ix+196+8 plates. (London: John Murray, 1932.) 10*s.* 6*d.* net.

THE author of this book so nicely adjusts the balance between weight of learning and popular interest that he charms the scholar and the arm-chair reader alike. The growth of legends and myths concerning animals is traced from the earliest European literature to the times in which science has destroyed belief in them, while leaving them to embroider literature.

The first sources of legends were oral, and many of these myths which appear in the early classics originated in Egypt or in south-west Asia. Oral tradition was supplemented by mythological and astronomical fancies, and animal symbolism became a feature of early civilisations.

Aristotle among the early writers was remarkable in that he used personal observation in dealing with the animal world, whereas later writers, up to the sixteenth century, culled their natural history from earlier records or tradition. The Alexandrian Christian writers used animals as emblems of ethical and religious truths, and such ideas spread over the whole intellectual tradition of literary nations, appearing in writings, architecture and heraldry. Collections of allegories, in which animals appear, were called bestiaries, and the wild imaginings were drawn from legends, classical sources and the Septuagint.

The use of such fables and allegories persisted all through the Middle Ages, although sometimes the appeal was worldly and unedifying rather than ethical. Dryden in the "Hind and the Panther" used the beast allegory in writing of the Roman Catholic and English Churches.

Many legends centre round the mysteries of birth and death. The ancients believed in spontaneous generation for insects, eels and worms, even to the time of Isaac Newton. The young of a bear was supposed to be born a formless lump and licked into shape by the mother's tongue—hence our expression 'an unlicked cub'; the reviewer confesses to a former belief that this referred to a lack of corporal punishment. The barnacle goose was believed to originate from deal planks soaked in salt water, from which grew barnacles; these in turn dropped young geese into the sea, and these last swam away to the fens and inland waters: this belief appears in English literature from A.D. 750 until the seventeenth century. The story of the Phœnix is traced from Egypt and occurs in literature from Hesiod's days—Aristotle indeed ignores it, but Tacitus, Tertullian and the Alexandrian fathers all give versions of it. The dragon was a monster common to the literature and beliefs of the whole world from the earliest times.

The history of the unicorn is instructive. It appeared as a distinct animal in the Septuagint, through a mis-translation of the Hebrew word 'reem' as 'unicorn' (Revised Version 'wild ox'), though the context shows that the animal was two-horned. The legendary one-horned beast was adopted widely, and Greek stories of a fierce one-horned Indian ass were transferred to it. This beast being reported as notably gentle to the female in the mating season, the legend grew up that the unicorn could only be subdued by a virgin. About Pliny's time the rhinoceros became known in Europe, and the facts about it and the legends of the unicorn became mingled, so that the subjugation of the rhinoceros by a virgin is related by Isidore in the seventh century. When later still, the narwhal's tusks, spirally twisted, were found on the shores of northern latitudes, they were hailed as unicorn's horns; these were supposed to possess magic curative powers, and the powdered horn was sold by apothecaries for more than ten times its weight in gold.

The basilisk appears in the Septuagint as a serpent, and by Pliny's time was a fearsome beast. Later we find the Englishman Neckam writing that a cock nearing old age lays an egg which is hatched by a toad, and from it emerges a basilisk. Vincent of Beauvais, and Glanvie, on the authority of the Venerable Bede, add to the beauty of the story by giving to the basilisk, thus hatched, the body of a cock and the tail of a serpent. By the fourteenth century we get the alternative name cockatrice, in Wycliff's Bible for example. This name probably came from the Latin 'crocodilus', through low Latin 'cocodrillus'.

Besides such legends, we have the interesting, if mistaken, beliefs in the power of the hyæna and the hare to change their sex, of the eagle to renew its youth, referred to by the Psalmist: in the super-devotion of the pelican, in the purposeful deafness of the adder.

What farmer of to-day would give credence to the statement that a collar made of the wood of the fig will subdue the wildest bull? Or that a stag draws forth snakes from their holes by the indrawing of his breath? The goat and deer family were stated, even by the cautious Aristotle, to use the herb dittany to eject wounding arrows from their bodies, and Pliny's statement that the blood of a goat would split a diamond into pieces was accepted without question. Pliny, too, refers to the belief that goats were never free from fever, folk-lore which is interesting because of the recently established connexion between goats and relapsing fever.

These and many other stories are enlivened by collotype illustrations from early manuscripts, herbals, etc. Surely every naturalist must appreciate the appearance and habits of these beasts and must feel a faint envy of his predecessors' ability 'to get away' with stories, untrammelled by cold facts.

Vitamins

Les vitamines. Par Mme. Lucie Randoin et Henri Simonnet. (Collection Armand Colin: Section de biologie, No. 145.) Pp. iv+220. (Paris: Armand Colin, 1932.) 10.50 francs.

TWO distinguished French workers in the field of vitamin chemistry and physiology have attempted in this little book a task the difficulty of which can probably be appreciated to the full only by those who have attempted the same or a similar one. To take a living and growing subject, especially in the biological sciences, and attempt to expound it to the non-technical reader, is to run one of two risks. Either everything may be made artificially simple by the use of too facile generalisation, by the suppression of inconsistencies and difficulties, by presenting as accepted facts what are actually only the author's interpretations of facts; or the saving clause and the citation of unexplained exceptions, the clumsy attempt to describe in words of one syllable what can only be defined neatly in words of many, the patronising parenthesis and the irritating footnote—all these may combine to scatter and confuse the reader. In the former case, technical colleagues look askance, and rightly: in the latter, non-technical readers turn away, and naturally.

Mme. Randoin and M. Simonnet have on the whole steered an admirably clear course between this Scylla and that Charybdis. If their treatment of the subject invites any serious criticism at all, it is for a little inconsistency of outlook as to the knowledge of their potential readers, and this is perhaps because they are *physiologists rather than* biochemists. Consequently they tend to indulge in undue detail of explanation when discussing the chemical aspects of vitamins and in undue use of medical phraseology when describing the clinical manifestations of deficiency diseases.

It is inherent in their subject that some of what the authors have written is already quite out of date, though their book was only published last year and they actually cite the results of research published in the middle of 1931—such as the preparation of crystalline vitamin D products. In spite of this, the book should prove an invaluable guide to those who wish to learn or to relearn the outlines of a subject increasing in importance and in the recognition of its importance. To the technical reader perhaps the most interesting feature will be the light shed by the book on the French view of the vitamin B complex—a view to which its authors have so largely contributed by their own investigations. Their insistence, too, that vitamin C is concerned with iron metabolism will come as a new conception to most English readers. But it is surprising to find such careful and up-to-date workers advocating without qualification the use of purified butter-fat in a rachitogenic diet (p. 91), more especially since their observations on p. 84, that "la vitamine à doser puisse être séparée de tous les autres principes alimentaires, lesquels ne doivent pas en contenir la moindre trace" illustrates unequivocally an essential principle of biochemical methodology.

The book shares with many books published in France the defect of having no index, but its general production and format call for little criticism, especially in view of its extremely low price. A. L. B.

Short Reviews

The Physics of High Pressure. By Prof. P. W. Bridgman. (International Text-Books of Exact Science.) Pp. vii+398+5 plates. (London: G. Bell and Sons, Ltd., 1931.) 22*s.* 6*d.* net.

PROF. BRIDGMAN has achieved an international reputation for his researches into the properties of matter under high pressures, so the volume under review is assured of a warm welcome by all who have studied the work which has been so assiduously pursued during the past twenty-five years. Prof. Bridgman is known personally to many on the eastern side of the Atlantic for in 1929 he gave the Guthrie lecture to the Physical Society.

Whilst the primary aim of the volume under review is to give a résumé of Prof. Bridgman's own work, the contributions of others are duly recorded. In the first chapter, which is of a historical character, will be found 12 pages of references to work on this subject antedating that of Prof. Bridgman's. The book constitutes a comprehensive handbook on the technique of physical measurements under enormous pressures; a technique which is highly specialised.

Although the subject at the present time is of purely scientific interest, the fact must not be overlooked that many chemical reactions are now being carried out under moderately high values of both pressure and temperature on an industrial scale, so the experience gained in the laboratory will in due course find application in the field of technology. The theoretical side of the subject has not advanced much but the quantitative description of a large number of high pressure phenomena may be expected to have some ultimate theoretical significance.

Prof. Bridgman tells a story of absorbing interest, the fare he provides is both interesting and enduring and the book may be recommended to those whose appetite has become jaded through a surfeit of speculative physics. In this volume we are told how pressure affects the various physical properties of matter such as the electrical resistance, the thermo-electric property, viscosity, the thermal conductivity, etc. E. G.

Fuel Testing: Laboratory Methods in Fuel Technology. By Godfrey W. Himus. Pp. x + 257 + 5 plates. (London: Leonard Hill, Ltd., 1932.) 15*s.* net.

MR. HIMUS, lecturer in fuel technology at the Imperial College of Science and Technology, has made it his business to collect the latest available data regarding this most important subject and put it together in a volume which forms a veritable treatise. It is refreshing to find a book which deals specifically and clearly with a single subject, and carries it through from A to Z.

Naturally, due to his associations with Prof. W. A. Bone's laboratory, the work done at that institution has received first consideration, but Mr. Himus also describes methods adopted by various other official institutions and private investigators which have been proved in practice to be suitable for the purpose in view. He describes in considerable detail and with all desirable clearness the various stages in fuel analysis, and whenever he deviates from the original investigator's rules and regulations he always carefully gives his reasons for doing so, and they are generally good enough to be accepted by anybody.

New fuels are coming into use every day for new purposes, and Mr. Himus's book, compact as it is, provides a valuable guide. It is well indexed, well illustrated, well printed, and should be found in the reference library of everybody interested in the winning and using of fuel.

The Case Against Einstein. By Arthur Lynch. Pp. xxx+275. (London: Philip Allan and Co., Ltd., n.d.) 10*s.* 6*d.* net.

Many thinkers, even among the "hierophantic display of the professors" who support Einstein, will be with Col. Lynch in some details of his enthusiastic criticism of the theory of relativity. The paradoxes of simultaneity, the variability of mass and the extraordinary properties of the space-time continuum, are stuffed with implications which need clarification. Einstein himself has said that his task is not yet completed. But it seems that Col. Lynch goes too far in asserting that the theory of relativity consists in giving to mathematical expressions strained meanings and in setting down as realities what are conventional modes of representing operations. In reading his book, one cannot make out whether it is addressed to the crowd, whom he despises, or to the learned, who share in his general impatience with all who disagree with him. In the first case, the author's plea would have been amusing if it was devoid of the specks of learning he places here and there. In the second case, Col. Lynch might have induced "the pundits" to give him a hearing, if he refrained from mixing his integrals with emotional remarks and irrelevant stories about himself and others. As it is presented, the book has, at times, an irritating flavour, where it could have been courageous and useful. T. G.

The Great Age of Discovery. Edited by A. P. Newton. Pp. xi+230+31 plates. (London: University of London Press, Ltd., 1932.) 15*s.* net.

The chapters of this book consist of a series of lectures given by seven different authorities in King's College, London, designed to cover the great movements in discovery during its most fruitful age. It is not, however, merely a series of disconnected episodes, since each great voyager is regarded in his historical setting and the whole gives a coherent view of the development of the map of the world during the late fifteenth and early sixteenth centuries. Each lecture is thoroughly documented with references to original sources and there are reproductions of old maps as well as other illustrations.

In his chapter on Columbus, Prof. Newton gives reasons for discarding the story about the Toscanelli letters, and is inclined to accept Vespucci's account of his second and third voyages and to suspend opinion on his first voyage. He believes that Tristan da Cunha and not South Georgia was the southern island that Vespucci claimed to have discovered in 1502. These are merely examples of the many problems that are reviewed throughout the volume.

Il polarografo: sua teoria e applicazioni. Per Giovanni Semerano. Pp. vii+207. (Padova: A. Draghi, 1932.) 16 lire.

The polarograph is an apparatus devised by Prof. Heyrovský and Dr. Shikata at the Charles University, Prague, to register automatically current-voltage curves during the electrolysis of solutions, using a cathode of dropping mercury.

By the aid of this apparatus, Heyrovský and his collaborators have made a series of investigations on 'polarographic analysis'. The method has not only been used in studying the deposition of metals from solutions of their salts but has also found application in elucidating some minor problems in such widely separated fields as biology (lymph and cutaneous diseases), sugar and petroleum technology and pharmacology.

In his very informative Italian monograph, Dr. Semerano describes the apparatus and its uses in the determination of deposition potentials, etc. He discusses the significance of the current maxima observed in certain circumstances and also gives an account of the applications of the method. More than a hundred papers on polarographic researches are cited in the bibliography.

The Map of England: or About England with an Ordnance Map. By Col. Sir Charles Close. Pp. x+166+8 plates. (London: Peter Davies, Ltd., 1932.) 6*s.* net.

To all who use Ordnance maps in the field this book should prove most attractive and full of indications for further exploration of the countryside. Broadly speaking, it consists of three parts. First comes a historical sketch of the mapping of Great Britain and the origin and growth of the Ordnance Survey. Next comes instruction in the reading of a map, which should enable many users of the map to find much more in it than they knew was there; and lastly, there are several chapters on the archæology of maps as expressed in place names, ancient buildings, fortifications, etc. These chapters are exceptionally interesting. The book is illustrated with a few photographs and reproductions of maps and there are useful bibliographical references to each chapter.

Phenomenal Regression to the Real Object

By DR. ROBERT H. THOULESS, Department of Psychology, University of Glasgow

FECHNER's law, that sensation intensity is proportional to the logarithm of the intensity of the stimulus divided by its absolute threshold value ($E=k\log(R/R_0)$) presupposes that there is a single sensation intensity for every stimulus strength. This is true not only of Fechner's law but also of any alternative law of the general form $E=f(R)$. Such invariable correspondence is only found, however, under artificially simplified conditions of perception. Under other conditions, it may break down at either of two points in the total process of perceiving: external stimulus → peripheral physiological process → central physiological process → phenomenon (that is, what is experienced).

A breakdown of correspondence between external stimulus and peripheral physiological process (that is, a condition in which a single intensity of stimulation does not provoke a single intensity of response in the sense organ) is to be found in the facts of contrast. In these, the intensity of the sense-organ's response is determined partly by the intensities of surrounding and of preceding stimuli. If, for example, two identical pieces of grey paper are seen against a white and a black background respectively, then the one on the white background seems the darker. That this is a change in the peripheral physiological process and not (as was once supposed) merely in the phenomenon, is shown by the fact that even in the after-sensation the difference persists; the after-sensation of the grey on the white background appears brighter than that of the other even when the after-sensations of the backgrounds are not themselves visible. Any assertion of a quantitative relationship between sensation and stimulus must, therefore, be stated for a definite condition of spatial and temporal background, since it is a theoretical possibility that a relationship determined for one condition of background may not hold for another.

Another set of conditions disturbing this relationship is universally present in ordinary everyday perceiving, although it may generally be eliminated from a laboratory experiment. Hering found that if a white paper was placed so much farther from a window than a grey paper that it reflected less light to the eye than the grey, it might nevertheless still appear brighter than the grey[1]. Here the breakdown in correspondence between stimulus and sensation proves to be between the peripheral physiological process and the resulting phenomenon. It is found that the after-sensations are equally bright when the illumination of the two papers is adjusted so that they reflect equal intensities of light to the eye, although the appearance of the papers is then of unequal brightness. Since the after-sensation is itself purely determined by the nature of the peripheral physiological process, it follows that (unlike the case of contrast) equal external stimuli are now producing equal retinal processes and the inequality of the resulting phenomena is introduced at a further stage of the perceptual process. Whether this is between the peripheral and the central physiological processes, or between the central processes and the resulting phenomena, there is, of course, no experimental method of finding out.

An extensive quantitative investigation of this tendency has been made by Katz[2], and Köhler has discovered that the reactions of hens and of chimpanzees show its effect[3]. The name originated by the German investigators—the tendency to *colour-constancy*—is, however, open to objection. Other experiments do not confirm the existence of any general law that phenomena tend to remain constant under varying stimulus conditions. The essential fact seems rather to be that the relative phenomenal brightness of two illuminated papers of different albedo is not determined solely by their relative luminosities (or the relative luminosities of their retinal images) but also by the 'real' or physical brightnesses of the papers (that is, their relative albedo). Phenomenal brightness is a compromise between stimulus brightness and 'real' brightness (albedo).

This principle is found to be widely true in visual perception, applying to the seen shapes of objects inclined at an angle to the observer, to the seen sizes of objects at different distances, to the degree of convergence of parallel-sided objects pointing from the observer, and to the colours of objects under different illuminations. A circle, for example, inclined at an angle to the observer is seen not as the ellipse which is its perspective projection (and also its retinal projection) but as a much wider ellipse which is a compromise between this stimulus shape and the real shape of the object[4]. Similarly, if two different sized objects are observed at different distances such that their apparent sizes are equal, this is not when they are making equal retinal images but when the retinal image of the actually smaller and nearer object is very much greater in size than that of the farther and larger object. Seen size is thus also a compromise between stimulus size and the real size of the object observed. These facts may be summarised as a tendency of phenomenal characters of objects visually perceived to regress from the characters given in peripheral stimulation towards the 'real' or physical characters of the object observed.

These effects can be much reduced or altogether eliminated by so simplifying the conditions of perception as to eliminate the perceptual cues to the real character of the object: by partially closing the eyes, completely closing one eye, or (still more effectively) by looking with one eye through a blackened tube cutting out surrounding objects. They return, however, when the ordinary method of perception is resumed. The results of these observations may be summed up in the form of a law: *When a stimulus which by itself would give rise to a certain phenomenal character is presented together with perceptual cues which indicate the physical character of the object, the resulting phenomenal character is neither that indicated by the stimulus alone nor that indicated by these perceptual cues, but is a compromise between them.*

The tendency to phenomenal regression may be most simply demonstrated to a person unfamiliar with it in the following way. He observes an elliptical object such as an elliptical table top with its long axis pointing towards the axis of his body. With both eyes fully open, he then adjusts the height of his head until the apparent shape of the object is circular. Then, keeping his head in the same position, he determines the perspective shape of the object by the usual method of closing one eye and measuring the projected short and long diameters by means of a pencil held out at arm's length at right angles to the line of vision. He finds that this projected shape is a very much flattened ellipse. The circular shape seen is a compromise between the flattened ellipse of the retinal projection and the elongated ellipse which is the real shape of the object.

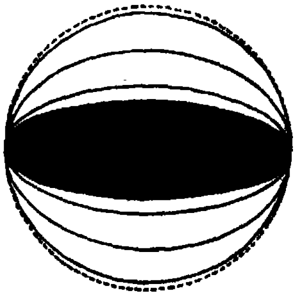

FIG. 1.—Phenomenal regression of inclined circle (median and extreme values for a group of 105 adult subjects).

The testing of a large number of subjects (nearly two hundred) has shown that these effects are to be found in all[5]. In no case was the phenomenon experienced identical with the stimulus character but always a compromise between this and the real character of the observed object. The amount of this dependence on the real object showed very wide individual differences. The extent of these differences is shown in Fig. 1 for an experiment on the perception of an inclined circle. The black inner figure is the plane projection of the circle at the angle of inclination at which it was observed. The central continuous elliptical line shows the average seen shape for the whole group of subjects, while the other two continuous lines show the extreme values of the seen shape for the subject who saw it nearest to the stimulus shape and to the real (circular) shape respectively.

The intercorrelations of the amount of this tendency to phenomenal regression in the perception of size, of shape, and of whiteness show that it behaves as a unitary mental function; the subject who sees close to the real character in one of these respects will tend also to see close to the real character in others. A large tendency to phenomenal regression amongst Eastern races may be an explanation of the absence of perspective and of shadows in Oriental art. The fact that a group of Indian students showed a significantly greater tendency to phenomenal regression than a control group of British students lends likelihood to this explanation.

In studying such facts as these, we are clearly outside that region of facts of sensory physiology for which alone Fechner's law has been stated. We are not, however, outside the region of legitimate quantitative experimental study, although we must not here expect to find simple quantitative laws of universal validity. The phenomenal fact which is not a fact of peripheral physiological process may reasonably be presumed to be a fact of central (cortical) physiology. Since, however, such cortical physiological processes are not at present open to direct study, these facts must be approached through a study of phenomena (that is, by the psychological method).

We may consider briefly a few of the practical applications of these principles. They have some bearing on the effectiveness of certain optical instruments. The usefulness of an astronomical telescope depends solely on its stimulus magnification. This, however, is not the case with a small pocket telescope bought, let us say, for looking at birds. The buyer wants the birds to look big so that they may seem near and lifelike. Mere peripheral magnification that does not attain this object is relatively ineffective. While a telescope magnifies the retinal image, it also diminishes phenomenal regression by introducing the condition of monocular observation through a blackened tube. The effect of phenomenal regression is apparently to make a distant object look larger and a near object look smaller. Elimination of phenomenal regression, therefore, reduces the apparent size of a far object, thus introducing a psychological factor antagonistic to the effect of magnification. So effective may this factor be, that, for a telescope of low power (as ×2), there may be no appreciable apparent magnification in ordinary use, although there is obvious reduction of apparent size if one looks through the wrong end. With higher powers, phenomenal magnification falls considerably short of retinal magnification for the same reason. The ordinary user may, therefore, find more satisfaction in the use of binoculars of relatively low power, since their wider field of view and the presence of distance cues through retinal disparation causes less elimination of phenomenal regression and so fuller psychical advantage from the magnification of the retinal image.

Another practical application of this principle is to be found in the projection of pictures. It has been said that the present television apparatus cannot be expected to give much satisfaction to the observer since the image is far too small—about four inches square. I have, however, several times measured the angle subtended by a cinema screen when at a distance at which the picture was quite as large as was necessary to appear life-like (to have gone much nearer would have made the screen look too big). Yet the side of the screen proved to be subtending an angle little more than half of that subtended by a square of four inch side if viewed from the ordinary distance for comfortable observation of ten inches. Obviously, therefore, it is not a defect of retinal size that makes the television picture ineffective. Phenomenal regression, which helps the distant cinema picture to look large, makes the near television picture look too small. The stray light in a cinema theatre which makes it possible to see the screen as a definite object at a definite distance, is serviceable to effective reproduction both by increasing apparent size and by resisting the tendency to distortion for people sitting somewhat to one side of the screen. For the near television picture this definiteness of location is a disadvantage, and it may safely be guessed that the television picture would gain in effectiveness if it were viewed monocularly inside a box totally black inside, although a cinema picture would lose in effectiveness and apparent size by such a condition of viewing.

Raman Spectra and Chemistry

WHEN a transparent substance is illuminated, a small fraction of the light is always scattered at right angles to the direction of the beam without undergoing a change in frequency, a phenomenon which is known as 'Rayleigh scattering'. In 1928, Sir C. V. Raman, who at the time was investigating the scattering of light by liquids, actually photographed the spectrum of the scattered light for benzene and similar substances when illuminated with a beam of monochromatic light, and found a number of new lines of low intensity, in addition to scattered light of unchanged wave-length (which represented normal Rayleigh scattering by the liquid). These new lines in the spectrum differed in frequency from the monochromatic light used by amounts which were characteristic of the scattering liquid, but were independent of the actual frequency used to excite them. This phenomenon is known as the 'Raman effect', and the new lines are termed the Raman lines of the substance, which we now know may be either a solid, a liquid, or a gas.

The significance of Raman spectra in chemistry formed the subject of a discussion held by the Chemical Society on February 16, which was opened by Dr. J. J. Fox. The field is one which has expanded enormously since Raman's original investigations, and has yielded results of great value both to physics and to chemistry. In the present article the chemist's point of view has been stressed, both in describing the cause of the Raman effect, and also in reviewing some of its possible applications.

The origin of the Raman effect is well illustrated by regarding the light incident on the scattering medium as a 'photon' of energy $h\nu_1$, where h is the Planck constant, and ν_1 is the frequency of the light. This photon may be considered as interacting with a molecule of the scattering substance, and as losing a part of its energy. As a result, the scattered light will have a lower energy $h\nu_2$, and its spectrum will contain a new line of frequency ν_2, which will be one of the Raman lines of the scattering substance. An amount of energy $h(\nu_1-\nu_2)$ must have gone to increase the energy of vibration or rotation of the molecule with which the photon collided. We know that this is what has happened, because of the close correspondence between the Raman frequency displacements $(\nu_1-\nu_2)$ and the rotational and vibrational frequencies of molecules, as deduced from infra-red absorption spectra. It is also possible for ν_2 to be greater than ν_1, if the photon can absorb energy from the molecule instead of imparting it. This 'anti-Stokes' scattering is less frequent than the normal Raman effect.

It is important to distinguish between the Raman effect and fluorescence, which results from the absorption of light energy, followed by a re-emission of radiation of a lower frequency, characteristic of the absorbing substance. For the production of fluorescence the exciting frequency must be greater than a minimum threshold value, and the fluorescent radiation will be of a fixed frequency if this criterion is satisfied. Fluorescence is of relatively rare occurrence, and is perhaps best known for solutions of certain dyes: it is obtained with atoms or molecules, whereas the Raman effect is observed only with molecules.

The correspondence between Raman frequencies and infra-red absorption spectra is well illustrated in the case of hydrogen chloride, which has an infra-red absorption band with its centre at 3·46μ. Wood found that hydrogen chloride has a Raman line with a frequency displacement of 2886 cm.$^{-1}$ (that is, 2886 wave numbers, this being a measure of the light frequency in terms of the number of waves per centimetre). This frequency corresponds with a wave displacement of 3·465μ, which is in exact agreement with the position of the centre of the infra-red absorption band. This result means that the Raman line in hydrogen chloride is due to the absorption of energy by the molecule, and its utilisation to increase the vibrational energy of the two atoms along the line joining them, without change in the rotational energy. Liquid hydrogen, on the other hand, shows Raman displacements of 354 cm.$^{-1}$ and

588 cm.$^{-1}$, and these two values agree closely with rotational frequencies of the hydrogen molecule, as deduced from the study of band spectra. In this case it is the rotational energy of the molecule which is increased. Non-polar molecules do not absorb light in the infra-red, but nevertheless, may show the Raman effect, which is of special use in such cases in calculating moments of inertia of the molecules and the distance between nuclei.

The Raman effect is generally investigated by using the mercury arc as a light source, one or more of the stronger lines being isolated by the use of light filters. The substance to be examined is then illuminated as intensely as possible, and the light scattered at right angles to the direction of illumination is examined with a large aperture spectrograph. The amount of scattered light is generally extremely small, and exposures of up to fifty hours are often needed to obtain satisfactory photographs of its spectrum. Numerous special types of apparatus have been devised, as, for example, in the examination of liquefied gases by McLennan, or in the study of single crystals. Many substances have been examined in solution, as the Raman spectra of solvent and solute will generally be superposed. Temperature changes have little effect, unless the molecular weight changes with the temperature, in which case it may be possible to observe lines characteristic of the simple and of the more complex molecules (for example, sulphur and sulphur trioxide). The effect of the physical state is also small in most cases, liquid water, ice, and water in the form of water of crystallisation, for example, showing almost the same Raman spectra.

From the large amount of experimental results already collected, it is possible to correlate certain definite Raman displacements with the existence of a particular vibrating group in a number of different molecules. Thus a Raman frequency of about 2900 cm.$^{-1}$ is observed (among other lines) for a large number of organic molecules such as CH_4, CH_3OH, and C_6H_6, and has been definitely associated with the vibration of a C—H linkage. Similarly, the C=O linkage is characterised by a Raman displacement of 1710 cm.$^{-1}$ in all ketones, and of 1730 cm.$^{-1}$ in esters, whilst a double bond between two carbon atoms always gives rise to a frequency of about 1600 cm.$^{-1}$. These frequencies undergo small but definite variations according to the nature of the rest of the molecule. Dr. Fox illustrated this in the case of the benzene frequency of 1600 cm.$^{-1}$, which undergoes a gradual decrease in the chlorine derivatives as the molecule becomes heavier, as shown below:

C_6H_6	C_6H_5Cl	$C_6H_4Cl_2$	$C_6H_3Cl_3$	$C_6H_2Cl_4$	C_6HCl_5	C_6Cl_6
1584	1580	1572	1560	1558	1553	1510 cm.$^{-1}$

This frequency has been attributed by Andrews[1] to the stretching of double bonds in the Kekulé benzene model. The Raman frequency will, in general, be between 2600 cm.$^{-1}$ and 4000 cm.$^{-1}$ if the vibrating pair is of the type X—H, less than 1200 cm.$^{-1}$ for X—X, 1200—1800 cm.$^{-1}$ for X=X, and 1800—2600 cm.$^{-1}$ for X≡X. These facts enable us to decide the structure of gaseous carbon monoxide, which has a Raman shift of 2155 cm.$^{-1}$, indicating a triple bond, and not a double bond of the ketone or ester type. A recent communication to NATURE directed attention to the Raman spectrum of nickel carbonyl, in which the triple bond frequency for the carbon—oxygen linkage was shown to persist.[2] Organic nitriles (R.C≡N) and isonitriles (of the type RN≡C) show Raman displacements of about 2250 cm.$^{-1}$ and 2160 cm.$^{-1}$ respectively, but hydrocyanic acid shows two frequencies at 2062 cm.$^{-1}$ and 2094 cm.$^{-1}$, the first of which may be attributed to a molecule HN≡C and the second to the tautomeric form HC≡N. The Raman spectrum of acetoacetic ester shows even more clearly the existence of the two tautomeric forms, since the ketone and the ester C=O frequencies (indicating the formula $CH_3\overset{\overset{\displaystyle O}{\|}}{C}.CH_2.COOC_2H_5$), and also the C=C and the OH frequencies (indicating a formula $CH_3.\overset{\overset{\displaystyle OH}{|}}{C}=CH.COOC_2H_5$) are observed.

$CH_3\overset{\overset{\displaystyle O}{\|}}{C}.CH_2.COOC_2H_5$

$CH_3.\overset{\overset{\displaystyle OH}{|}}{C}=CH.COOC_2H_5$

An interesting study of the ionisation of nitric acid has been made by Rao.[3] At a concentration of more than 65 per cent, the acid shows a Raman line at about 1300 cm.$^{-1}$, due to the NO_2 group, which is also observed in nitrites, nitrobenzene, nitromethane, and similar compounds. Only on dilution is the line at 1050 cm.$^{-1}$, which is characteristic of the NO_3 ion in solutions or in crystalline nitrates, observed. This would indicate that the strong acid has the formula NO_2OH, a fact which harmonises with its nitrating action on organic compounds. Rao has claimed that the intensity of the line due to the NO_3 ion may be used as an approximate measure of the degree of ionisation of the acid. A similar phenomenon is observed with sulphuric acid. The acid of strength above 25 per cent shows a line at 1046 cm.$^{-1}$, which is attributed to the (HSO_4) ion, since it appears prominently in solutions of potassium hydrogen sulphate $(KHSO_4)$. At concentrations less than 25 per cent, a Raman line due to the $(SO_4)''$ ion makes its appearance. It is observed in solutions of sulphates, irrespective of the cation, and also in crystalline sulphates.

Dadieu and Kohlrausch have used the vibrational Raman frequencies, which may, in many cases, be associated with interatomic linkages in molecules, as a means of calculating the strength of binding of the two atoms. By treating the vibrating pair as a simple harmonic oscillator, it is possible to calculate the restoring force per unit displacement. The amplitude of the oscillation may also be derived, the product of these two quantities measuring the binding force. As calculated by this method, the strength of single, double, and triple chemical bonds are in the ratio 1 : 2 : 3. It is possible to calculate absolute values of the strength of linkage from the relative values, if some one absolute value is known (for example, for the C—H linkage in the benzene ring, a value of 101,000 cal. per gram molecule may be used).

The discovery of the Raman effect is so recent that it is not surprising to find that theory has lagged behind experiment. Raman spectra may often be photographed with relative ease, but up to the present, the results have only been interpreted fully in the case of some of the simpler molecules, of which carbon tetrachloride may be taken as an example. Very careful examination of the Raman effect for substances of this type, and particularly, intensity and polarisation measurements for the individual Raman lines, makes it possible to determine all of the fundamental vibrations in the molecule. This problem becomes more and more difficult as the molecule increases in complexity, but there can be little doubt that, in time, the subject will develop to a point where the chemist will be able to consider the molecule as a dynamic rather than a static system. In the meantime, we may anticipate that the accumulation of Raman spectrum data will continue, and that they will be applied to solve many problems of molecular constitution.

Obituary

PROF. PAOLO ENRIQUES

PAOLO ENRIQUES, who died on December 26, had held the chair of zoology and comparative anatomy at the University of Padua since 1921, and was the leader of Italian zoologists along the lines of genetic, physiological, and philosophical research. Born at Leghorn on August 17, 1878, he pursued his university studies at Florence, Rome, and Bologna, devoting four years to medicine, in which he qualified at Göttingen, and two to natural science, in which he took the doctor's degree at Bologna in 1901. In the following years he lectured at Florence on the philosophical approach to biology, at Sassari in medicine and later on comparative anatomy. While professor at Padua he also taught under the Faculty of Medicine in the Schools of Pharmacy and of Social Science, and for some years lectured on genetics applied to the breeding of silkworms at the Silkworm Station of Brusegana.

Besides a number of papers on various organs of Mollusca in their functional aspect, on reproduction in Protozoa, on the nucleus of Radiolaria, and similar subjects, Prof. Enriques published several works of wider scope. That which shows most clearly his critical and constructive thought is "La Teoria Cellulare" (Bologna, 1911), in which he attempted a synthesis of modern biological problems. In "Eredita nell' uomo" (1922) he brought to bear on the subject his medical knowledge of pathological characters, while in "Riproduzione dei Protozoi" (1922) he resumed the researches of himself and his pupils, which led to conclusions of fundamental importance, particularly regarding the biological cycle of the Infusoria. His "Trattato di Zoologia e di Anatomia Comparata" has been adopted in many Italian and some foreign universities. In a monograph on Mendel's laws and chromosomes, Enriques summarised the researches of the previous fifty years, and deduced from them new laws, adding to the three classic laws of Mendel a fourth law of independent variability based on his study of variability in radiolarian species, as well as various synthetic statements of the phenomena associated with sex and sex-linked characters. In 1928 he communicated to the Istituto Veneto his "Teoria della Ciclogenesi", in which the difference between plants and animals was set on a new basis.

In a recent series of six "Contributi alla Teoria dell' Evoluzione" Enriques urged that heredity and evolution are not irreconcilable facts but that the phenomena are explicable by his fourth law of heredity. Not many months ago there appeared the three volumes of *Atti* of the eleventh International Congress of Zoology, to editing which he had devoted all his energies; they contain 1,500 pages and 38 plates. Herein are published summaries of some of his previous studies, as well as a proposed classification of Radiolaria. This last anticipates the classification to be followed in his monograph on the Radiolaria of the Gulf of Naples, a great work unfortunately left incomplete. Other books now in press are a translation of "The Biological Basis of Human Nature" by Jennings, and "Il problema della Vita" which purports to give in intelligible language a synthetic review of all the problems of biology considered in their manifold aspects—physical, chemical, morphological, and philosophical.

The value of Enriques' work was widely recognised: he presided over both the Unione Zoologica Italiana and the Accademia Scientifica Veneto-Trentino-Istriana from 1928 until 1930; he was honorary vice-president of the International Congress of Genetics at Ithaca, United States, and president of the International Zoological Congress at Padua in 1930. There one saw the magnificent Institute of Zoology that had just been completed under his direction, and there the representative of Great Britain had abundant opportunities of appreciating his powers of oratory, his clarity of exposition, his originality of thought, and, beyond these, his friendly hospitality, his goodness of heart, and his devotion to the highest ideals of science.

The academic term was over; Enriques had started in his motor-car for Naples to continue his researches on Radiolaria; he was alone on the road that led across the Campagna, when an accident overturned his car; he was picked up and taken back to Rome, where he lay in hospital for a week; his recovery was looked for, but on Christmas Day, meningitis supervened, and he died on December 26. Thus all too early have Italy and the world lost one who, to adapt his own words, exhibited "un temperamento passionale che si affigge in una idea grande e la persegue con ricerche e scoperte, o grandi o piccole secondo le sue forze, ma sempre avendo dinanzi la spiegazione generale e profonda della natura". F. A. B.

SIR DANIEL MORRIS, K.C.M.G.

THE death of Sir Daniel Morris, in his eighty-ninth year, brings to a close a long life devoted to the public service; but it is his work for the Empire, as Imperial Commissioner of Agriculture in the West Indies, that will be kept especially in grateful remembrance.

Except for the twelve years (1886–1898), when he was assistant director at Kew, under Sir William Thiselton-Dyer, Morris's work and interests had lain overseas in the Colonies, and while he held the assistant-directorship he was seconded to undertake a special mission to the West Indies (1890–91), in connexion with the development of the fibre, sugar and banana industries in particular; again, in 1895, he visited the Bahamas and the following year he was appointed expert adviser to the commissioners on agricultural and botanical questions, when the West Indian Royal Commission was sent out during Mr. Chamberlain's fruitful time at the Colonial Office. His valuable services were very fittingly recognised by his appointment as Imperial Commissioner of Agriculture in 1898. During the ten years he occupied this important post, he enlisted the services of a staff of experts to teach and advise in the Leeward and Windward Islands, and was able to bring about co-operation between the various islands and develop their agricultural industries on sound lines.

Among other valuable undertakings Morris's personal introduction of Sea Island cotton to the Islands was a signal achievement; to him also is due the improvement of the sugar cane by hybridisation, and the extension of the cultivation of limes and *Cacao* and other tropical products. The inter-colonial agricultural conferences which he established have done much good work, mainly in bringing together the agricultural officers and planters in the Islands and so helping to co-ordinate and stimulate their efforts.

Morris received the honour of the C.M.G., in 1893 "in recognition of Scientific and Economic Services rendered to Her Majesty's Colonies", and in 1903 he was advanced to K.C.M.G.

Before Morris went to Kew in 1886, he spent two years in Ceylon (1877–79), working on the coffee disease as assistant to Dr. Thwaites, and from there he was promoted to be director of Public Gardens and Plantations, Jamaica, a post he held for seven years. While holding this post he visited British Honduras, in 1882, and St. Helena in 1883. His report on the economic possibilities of St. Helena is a valuable document which, had it been followed up in practice, would have been of great benefit to the island.

While at Kew, Morris was treasurer of the Royal Horticultural Society from 1888 until 1891, and took an active part in the affairs of the Society at a critical time. He was enrolled a Victoria medallist of the Society and for many years was one of the vice-presidents.

Since his retirement Sir Daniel Morris was, until his health began to fail, an active member of the governing bodies of the Imperial Institutes of Entomology and Mycology, and of the John Innes Horticultural Institution. In Bournemouth, where he settled on his return home from the West Indies, he quickly entered into the scientific life of the community, and the present flourishing condition of the Bournemouth Natural Science Society is largely due to his keen and stimulating interest.

Morris's published papers deal mainly with botanical or agricultural matters of economic importance and are valuable works of reference. Very possibly much of the good work he was able to carry out was due to his skill as a speaker, for he was a lecturer as well as a writer of unusual ability. Lady Morris, who was his able ally for more than fifty-two years, died in January of last year.

DR. JOHN R. FREEMAN

FROM *Earthquake Notes* for December 1932, issued by the Eastern Section of the Seismological Society of America, we learn of the death of Dr. John R. Freeman on October 6, 1932.

Dr. Freeman was consulting engineer to several important engineering concerns in the United States. He was president of the American Society of Mechanical Engineers in 1904 and of the Society of Civil Engineers in 1921. He did much work in connexion with water engineering and fire protection. Dr. Freeman studied earthquakes from the engineer's point of view. His principal works are his detailed study of the Melfi (Italy) earthquake of July 23, 1930, and his great book on "Earthquake Damage and Earthquake Insurance", published last year, in which he made valuable contributions to the problem of earthquake insurance in the United States.

WE regret to announce the following deaths:

Prof. T. Alexander, formerly professor of engineering at Trinity College, Dublin, on February 17, aged eighty-five years.

Lord Lovat, K.T., G.C.V.O., K.C.M.G., formerly chairman of the Forestry Commission, who has done much work in connexion with the development of forestry throughout the British Empire, on February 18, aged sixty-one years.

Dr. A. D. Risteen, director of technical research in the Travelers Insurance Co., known for his work on industrial technology and safety, on December 30, aged sixty-six years.

Dr. John Watts, of the old Chemistry Department of the University of Oxford, author of memoirs on the industrial uses of tannins, on February 9, aged eighty-nine years.

News and Views

Christ's Hospital and Samuel Pepys

REFERENCE was made in the article on Pepys in NATURE of February 18 to his association with the Royal Mathematical School of Christ's Hospital, and the circumstances attending the foundation of the School are worth recalling. The project for a naval seminary, communicated to Charles II for his approval, was backed, in the first instance, by Sir Robert Clayton, Sir Jonas Moore, and Sir Christopher Wren; afterwards they were materially assisted by Pepys. Sir Jonas Moore was Surveyor General of the Ordnance and he solicited the favour of the Duke of York, then Lord High Admiral. A royal charter was granted and the School was opened in 1673 for forty boys. Little was done, however, by King Charles towards its maintenance, and the foundation suffered many vicissitudes. Pepys offered various objections from time to time to what he deemed inefficient methods of administration and teaching, and when, in 1698, he was appointed vice-president, he turned his attention to the re-modelling of the Mathematical School. The following is an extract from a letter of Pepys to the governors, dated May 4, 1694:—". . . when, in the yeare 1676 a shipp of the King's (with another of certain private adventurers) design'd upon an Expedition for Discovery of a passage by the N.E. to China; wherein his then majesty had reason to expect many unusual occurrences, and therefore fit for a Child of this Foundation to share in the first advantage of: He was pleased to communicate his pleasure in it to the Hospital. In which, provision was made for the child's being not only well instructed in his service during the voyage . . . but returned at the end of it; as he accordingly was, and by us afterwards bound apprentice to a Merchant Man, Bartholomew Clement, Master of the Ffortune, tradeing to Virginia". In April 1699, Pepys was presented with the freedom of the City of London "in acknowledgment of the great zeal and concern for the interest of Christ's Hospital which he hath manifested on all occasions".

The Marquis of Worcester at Vauxhall

AMONG those pioneers of the use of steam for pumping who have found a place in engineering history is Edward Somerset, second Marquis of Worcester (1601–67), whose life was written in 1865 by the civil engineer, Henry Dircks (1806–73). The Marquis lived in troubled times but all his life was interested in mechanics, and in 1663 published his "Century of Inventions", containing notes in vague and mysterious language on inventions to be tried and perfected. Quite early in life, with the German master mechanic, Caspar Kaltoff, he became connected with the Ordnance Factory founded by Charles I at Vauxhall and on this site later in life he proposed to found a college for training artisans, and erected his famous 'water commanding engine', which attracted considerable attention. The interest surrounding the projects and achievements of the Marquis led Mr. W. H. Thorpe to attempt to determine the exact site of the works at Vauxhall, and in a paper read to the Newcomen Society on February 15, he gave an account of his researches and their results. The position of the property was, he said, indicated by a petition dated 1666 presented to Charles II by the Marquis, and the details of the property are described in a report made by the Surveyor General to the Duchy of Cornwall. Further evidence was obtained from Rocque's large-scale "Survey of London" made in 1739–45. For a description of the apparatus for pumping erected at Vauxhall, we are indebted to two foreigners who saw it, but neither of them refers to the use of steam. One of the notes in the "Century", however, refers to "an admirable and most forcible way to drive up water by fire", and it is this that gives the Marquis of Worcester his place among pioneers of the steam engine.

Industry and Electrical Research

THE twelfth annual report of the British Electrical and Allied Industries Association (E.R.A.) presented at the annual luncheon on February 15 is satisfactory and interesting. A period of depression in commerce often means greater activity in development. The report shows that there are seventy-seven committees actively engaged in advising and directing research on problems of urgent importance to industry. An incidental advantage is the benefit that accrues to individuals who share in the constant exchange of views which takes place at these specialist committee meetings. At the start, the organisation was almost entirely based on the sections of the industry connected with manufacturing. Its activities have now widened very much and there are very few electrotechnical problems outside its sphere. The Association was never designed to relieve manufacturing works of the necessity of solving their own specific problems. The report proves that many of the subjects considered interest several branches of the industry. The financial statement shows that the main contributions, so far as money is concerned, now come from the electric supply companies, railway groups, etc. Although the actual income for last year was greater than the preceding year, yet the Association has adopted a conservative policy, maintaining its organisation intact, expediting the completion of researches and advancing the plans for new work. Many members of the permanent staff have been engaged solely in scientific investigations and the reports they have published have been useful to the industry.

MATERIAL progress has been made during the year towards ascertaining the real properties of dielectrics, as distinct from empirical measurements of their behaviour under given conditions. Numerous commercial problems are under investigation, as, for example, the study of radio condensers in co-operation with the British Broadcasting Corporation. Improved efficiencies in steam generating plant have been effected mainly by a better knowledge of the properties of steam and studies on the creep of metals. Important conclusions have been arrived at by researches on wind pressure on overhead lines, heating of buried cables and cables in ducts, the armouring of cables and methods of efficient earthing. The work done on the design and use of concrete poles may lead the Electricity Commissioners to reconsider the present stringent regulations relating to their use. Important advances have been made in new types of switches to break large currents at high voltages. We are now abreast of the work done in competing countries and in some directions we are in advance. Thanks to experimental research and advanced mathematical calculations, the problem of the interference caused by power circuits on communication circuits can now be regarded as solved. Good progress has been made in the study of problems of importance in railway engineering. The printed schedule of headings under which the railway researches are being conducted now runs to twenty pages.

Training the University Graduate

IN the annual report presented by the Vice-Chancellor, Sir Charles Grant Robertson, to the court of governors of the University of Birmingham on February 23 comment is made on the increase in the number of students in spite of the general depression. It is pointed out that on the Continent, the universities are greatly congested, the attendances being, paradoxically, greater the greater the depression. The chief increase is in the faculty of medicine. The Vice-Chancellor raises the question whether the universities are doing all that they might or ought to do to meet the requirements of the rapidly changing social conditions. For example: "if the Universities are providing, and will have to provide to an increasing extent, direct training for careers, not contemplated twenty years ago, and those careers require a special technique, the essential problem is as to whether that technique can be *taught*, or whether the true function of the University lies in preparing for the most rapid acquisition of the technique elsewhere and as a post-graduate business. 'Technocracy' is the latest American gift, and we may fear the United States—especially as a giver—but do we not need as a nation, *outside* the Universities but definitely correlated to them, a series of 'schools' which will do for the University graduate, who has not been like the engineer technologically trained, what the Hospital does for the medical graduate who becomes, for a strictly limited period, a House Physician and a House Surgeon? Do we not also need a much closer connexion between the big Technical Colleges and Schools and the Universities?" In referring to the report of the Joint Standing Committee on Research, the Vice-Chancellor gives his opinion that "the Committee ought to be in a position to support a plan of research conducted *by a Department* as a whole on definite lines and for a definite purpose and extending over a defined period". The only obstacle to such a policy is of course the financial one.

Specialist Posts in Industrial Management

AN article by Dr. W. H. Coates in the January number of the *Journal of Careers* reviews the developments in industry which have led to the creation of specialised posts in industrial management. These developments are the outcome of the changed conditions of industry and the heavier demands upon human qualities in management which are made by the growth of the scale of industrial enterprise and organisation. Where formerly several men filled one function in several small businesses, there are now several men each specialising in one function in large-scale business. These specialised activities can be broadly classified as they are concerned with production, sales or administration. We thus have the new key positions such as planning and production manager, transport manager, sales manager, secretary, personnel manager, labour officer, purchasing officer, etc. Specialisation in this way, concentration of research, thought, and practice within a limited field, is steadily leading to more efficient management, to fuller knowledge and to new ideas, and affords also a way of applying the scientific method to an increasing extent to the problems of administrative and executive control. Dr. Coates visualises alike a large field in which scientific methods have to be applied with an accuracy, patience and persistence comparable with those applied in the fields of physical science, and a field of human co-operation which makes large demands upon team work if the problems of large-scale industrial management are to be solved. Given such conditions, Dr. Coates sees no limits to successful management implicit in the size of the undertaking, and is confident that there is no lack of young men who are capable of tackling the present and future problems of large-scale management.

Fat in Æstivating Animals

IT is a matter of common knowledge that many hibernating animals, in cold climates, survive their long and enforced fast by accumulating fat within the body, or immediately under the skin. It is by no means so generally realised that a precisely similar accumulation is made by many animals living in hot climates, which must also fast, in a state of æstivation, until food is again procurable. A good opportunity of making observations on some æstivating types has just been furnished by the birth at the Gardens of the Zoological Society of London of four 'fat-sand-mice' (*Steatomys*) and four 'fat-tailed gerbils' (*Pachyurus*). For this curious adjustment has now apparently become fixed, since even in captivity the fat is still stored, though its need has disappeared. But there seem to be no records as to whether the amount of fat formed is less in captive animals, which have no need to fast, and at what stage in the growth of the young animal it begins to make its appearance. There seem to be no possible means of discovering why, in these two types, living under precisely similar conditions, one should form a deposit of fat over the greater part of the body, while in the other it should accumulate in the lower part of the back and tail.

Candles and Candlemaking

THE science and art of illumination are nothing if not progressive and the displacement of the candle, emblem of humble domesticity and spiritual occasions, by other forms of light is but one of the inevitable consequences of modern progress. Candle manufacture is casually regarded as a minor industry to-day, but such is actually not the fact as Mr. David Allan showed in his paper on this subject before the Institution of Petroleum Technologists on February 14. The candle has had a firm place in history and religion since ancient times. Its simplicity of construction and self-contained character have commended it for use in diverse circumstances where soft and easy illumination have been required. Essentially a cylinder of fat or wax enveloping a fibrous core or wick, cast in various shapes and sizes, its form has varied but little throughout the ages. Attention latterly has been paid chiefly to efficiency and cheapening of methods of manufacture, while a measure of artistic evolution is discernible in the shapeliness of form and decorative effects achieved in the modern product. The candle industry, in so far as it relates to manufacturing process, is a comparatively straightforward matter, but the technology behind it is by no means so simple. The author has done good service, not only by presenting a comprehensive account of the subject, but also in describing the essential technology. While the petroleum industry cannot claim the candle as entirely its own product, the paper shows clearly that this article of commerce is by no means one of minor importance, and the link between hydrocarbon oils and saponifiable fats and waxes is once again well illustrated by its technical study and description.

Safety of Life from Fire

A USEFUL lecture given by Col. G. Simonds at the Royal Society of Arts on "Safety of Life from Fire" is published in the Society's *Journal* for January 20. The figures given prove that the fire risk to individuals is not large, but as the risk can be almost eliminated by a few simple common-sense rules, it is advisable that they be taught in schools. The best way of doing this is by showing films illustrating the principal dangers and the methods of avoiding them. The dangers to life arise mainly from the products of the fire, namely, smoke and hot gases. During a fire, it is a safe rule never to open a door if a fire is raging the other side. If it is necessary, and the door opens towards you, one hand should be placed on the handle and the other shoulder high on the door. The door can then be opened safely about three inches, the opener being protected from the smoke and gases and so see something of the surroundings. If necessary, the door can be shut quite easily. To go through smoke one should crawl on the hands and knees keeping the mouth as close to the floor as possible. When coming down a staircase through fire or smoke one should keep as close to the wall as possible and if it is necessary to crawl, come down feet first. A person whose clothes are on fire should never be allowed to remain standing for a moment. Fatalities nearly always arise from the shock of burning about the face and head. If they should start to run they should be tripped up and rolled on the floor in a coat or a blanket if possible. The new tannic acid treatment for burns has proved very successful, as shown by Dr. Philip H. Mitchiner in his Hunterian lecture delivered before the Royal College of Surgeons on February 1 (*Lancet*, Feb. 4, p. 233). The results of its use show a very decided percentage drop in the number of fatal cases. People should be warned about the dangers of cleaning with petrol as the number of fatalities due to this cause is increasing.

Ultra-Short-Wave Radio Research

Two papers, communicated by the General Electric Co.'s research laboratories at Wembley, were read to the Radio Section of the Institution of Electrical Engineers on January 4 by Mr. E. C. S. Megaw. The first paper gives a critical summary of the existing knowledge of electronic oscillations. The methods of their production are outlined and their applications to radio communication are described. Using these oscillators and parabolic reflectors, Beauvais obtained in 1930 a maximum range of telegraphic transmission of about 25 miles from the top of the Eiffel Tower. In the Dover-Calais demonstrations of the International Telegraph and Telephone Laboratories (March 31, 1931) duplex telephony was achieved over a similar distance. In the second paper, possible methods of utilising magnetrons to generate short-wave oscillations are indicated and the more important of the results obtained by previous workers are described. Experimental investigations were undertaken to discover the relations between electron and dynatron types of oscillation. For electronic oscillations it was found that the experimental results are entirely in agreement with theory in those cases where it is applicable. The investigation of the simple dynatron oscillations showed that the static characteristics exhibited a negative resistance effect. During oscillations it was found that the anode current may exceed the original total emission current. This is considered to be due to the bombardment of the filaments by electrons which return to it with considerable velocity. The shortest wave-length obtained by means of dynatron oscillations was about thirty centimetres. At this wave-length the power attainable was about a tenth of a watt. It is concluded that for wave-lengths less than about fifty centimetres electronic oscillations give the greatest output.

Mortality from Whooping Cough

IN a paper read at a meeting of the Royal Statistical Society on February 21, Dr. Bradford Hill pointed out that, in modern times, mortality from whooping cough in England and Wales has shown a remarkable decline, the death rate in the years 1921–30 being only one-third of that recorded in 1861–70. In spite of this improvement it remains a very important cause of child mortality. In 1921–30 it was responsible in England and Wales for no less than 44,000 deaths, or nearly 1 per cent of the total mortality of the population. The mortality falls mainly upon the first two years of life, while, in 1921–30, more than 90 per cent of the deaths were concentrated on the first five years, a ratio which was equally true at the end of the eighteenth century. In view of this concentration upon very young children, steps to control it are earnestly to be desired. One of the most curious anomalies of whooping-cough mortality, which has long been recognised, is the consistently heavier mortality of female children. Various attempts have been made in the past to explain this, for example, in terms of the sex differences in the formation and development of the larynx, sex differences in sensitiveness of the nervous system, but none of the hypotheses so far put forward seems, on careful examination, to be adequate.

Another curious feature of the mortality of infants from whooping cough is the lower death rates of illegitimate infants, when compared with the legitimate, in the first three months of life, while at the same age lower death rates are found in urban districts when compared with rural. An abnormal characteristic of the epidemiology of the disease, that has existed for at least three quarters of a century, is the increasing proportion of early deaths with decreasing urbanisation. This feature of the disease is not shown by measles. The latter acts according to 'expectation', namely, the more the 'overcrowding' the earlier the liability to attack and death. Yet whooping-cough statistics for England and Wales suggest the reverse. The relative importance to-day of whooping cough as a cause of widespread sickness and death is perhaps still under-rated, and further steps to combat it are required.

British Claims in the Antarctic

By an Order in Council dated February 7 and published in the *London Gazette* of February 14, a sector of the antarctic comprising an extent of one hundred and fifteen degrees of longitude and covering more than a quarter of the antarctic continent has been placed under the authority of the Commonwealth of Australia. The *Times* reports the order as stating that "that part of the territory in Antarctic Seas which comprises all the islands and territories other than Adélie Land situated south of the 60th degree of South Latitude and lying between 160° E. and 45° E. is territory over which His Majesty has sovereign rights". The order comes into force when the necessary legislation has been passed by the Commonwealth Parliament. Adélie Land was claimed by France in 1924 but its boundaries were not defined. The new territory adjoins the Ross Dependency of New Zealand on the east and extends from Oates Land through King George, Wilkes, Banzare, Knox, Queen Mary, Wilhelm, and MacRobertson Lands to Enderby Land, beyond which Norwegian discoveries link it to Coats Land. The coasts of most of the territory were discovered by British, including Australian, and American explorers. The glaciated interior is unknown. No one name is in use for the whole of the area. The only commercial value of the coasts is for whaling.

The Shrimp Industry of Leigh-on-Sea

Under this title Mr. A. Laurence Wells has written a long and comprehensive account of this once important industry of the Thames Estuary (*Southend Standard*, Dec. 29, 1932, Jan. 5 and 12, 1933). Unfortunately, shrimping at Leigh has steadily dwindled since the beginning of this century. From six boats in 1832, the numbers rose to a hundred in 1850 and two hundred in 1875, dropping from 1905 to the present time, when there are only sixteen shrimpers among the forty boats engaged in fishing activities. These records of a vanishing industry are well worth preserving and Mr. Wells with the help of the manuscript notes now safely preserved in the Southend Museum made by the late Dr. James Murie gives us a most interesting survey both historical and biological. The term 'shrimp' embraces several species which are all described and differentiated. Thus from this district we have the common 'brown shrimp', the original shrimp of commerce, at first the only kind fished; the 'banded shrimp', the 'yellow shrimp' and the 'channelled shrimp'. Besides these true shrimps there is the 'pink shrimp' which, though not a prawn, is prawn-like, and four species of real prawns. Finally, there is *Nika edulis*, the so-called 'Risso's shrimp' which, although rather rare, is very good to eat. Each of these has its own individual habitat. Their life-histories are different and the fisherman knows a great deal about them which is not known to the general naturalist. There is much valuable information in this series of articles which all interested would do well to study.

Aquaria

The importance of observing the hydrogen ion concentration in the aquarium is now fully recognised. Both the *Aquarist and Pond Keeper* of January–February 1933, and the *Aquarium Review* of December 1932, include articles on this subject ("*PH* Values, Their Meaning and their Significance to the Aquarist", by J. F. Corrigan. "The Aquarium and *p*H" by L. C. Mandeville). The same number of the *Aquarist* contains notes from the Brighton Aquarium by the Curator, Mr. George W. Weller, and notes from the Zoological Society's aquarium by the Director, Mr. E. G. Boulenger. In the Brighton Aquarium there are now living one hundred and twenty herrings; also an angler, *Lophius piscatorius*, which is very difficult to keep alive and one of the most voracious of all fishes. Mr. Lester L. Swift gives a very interesting account of the American tropical fishes belonging to the genus *Mollienesia*, and how to keep and rear them. These fishes are viviparous but somewhat difficult and irregular in breeding in captivity. They require much vegetable food as well as animal, and a certain kind of slimy alga, known as 'frog-spit', is apparently essential to the raising of healthy broods. A female may have 2–10 young every few days for a month or she may have a litter once a year or once a month for several months in succession.

Journal of Chemical Physics

THE first number of the new American *Journal of Chemical Physics*, which is published by the American Institute of Physics and has an editorial board comprising the leading American chemists and physicists, contains a number of important papers. In a brief editorial introduction, Prof. H. C. Urey, the managing editor, states that the journal caters for an increasing number of investigators who are working on subjects on the border-line between physics and chemistry, who have a broad knowledge of both sciences and are using methods of investigation which belong neither to classical chemistry nor to traditional physics. The papers in the new journal, which has an attractive format and is well printed in double-column pages, include contributions by Langmuir on an extension of the phase rule for adsorption, by Debye on the mass of electrolytic ions, by G. N. Lewis on the chemical bond, by Harkins and Jackson on a spectroscopic study of the decomposition and synthesis of organic compounds by electrical discharges, by Pauling on helium molecule ions, and several other important communications on physics and physical chemistry. It is clear that a high standard has been set in the new journal, and although the multiplicity of chemical and physico-chemical journals, especially in Germany and the United States, presents a serious economic problem to scientific institutions, the *Journal of Chemical Physics* should be welcomed as an authoritative medium for the publication of work which is interesting both to chemists and physicists.

World Petroleum Congress

A WORLD Petroleum Congress, organised by the Institution of Petroleum Technologists, is to be held in London on July 19–25. Membership is open to all persons connected with, and interested in, the petroleum industry, at a nominal fee of 10*s*. It is proposed to hold the sessions of the Congress at the Imperial College of Science and Technology, South Kensington, and the scope of activities on this occasion includes the reading of various technical papers, a private view of the International Oil Industry's Exhibition, exhibition of films illustrating the petroleum industry and sundry social arrangements. Foreign delegates from all important oil-producing countries are being invited and the Congress will offer an excellent opportunity for the interchange of ideas, both technical and economical. Broadly speaking, the technical programme will embrace four main sections of the industry, geological, engineering, refining and chemical, and standardisation. From the preliminary announcements available, it would seem that this Congress, by its purpose and very wide appeal, will be one of the most important international functions affecting the petroleum industry which has been held for many years, and it is a matter of gratification that, on this occasion, it has both a British sponsorship and setting.

Atoms, Molecules and the Atmosphere

FOR his presidential address before the Royal Meteorological Society, on February 15, Prof. S. Chapman took as his subject, "Atoms, Molecules and the Atmosphere". While the molecular constitution of air can be ignored in considering most meteorological problems of the lower atmosphere, it is of great importance for the phenomena of the upper atmosphere. The remarkable advances made in recent years in our knowledge of the intimate constitution of matter bear closely on many problems of upper-atmospheric physics. For this reason a broad summary of modern views on atomic and molecular structure was given, bearing on their states of excitation, ionisation, and dissociation, on the spectra that they emit, and on the effects of impacts between particles of various kinds, electrons, atoms, molecules and ions. Brief mention was made of some atmospheric phenomena in which such considerations are of importance—the spectra of the aurora, and of absorption bands produced by oxygen, ozone, and water; the dissociation of oxygen in the upper atmosphere; and the ionisation of the upper air.

Gypsy Art in Russia

AFTER a period of eclipse following the revolution, the characteristic music of the Russian Gypsies has been revived on lines, it is claimed, more in accordance with its distinctive racial peculiarities than were the Russianised music and singing of the town Gypsies popular under the Tsarist regime. According to an account by M. A. Barannikov (*J. Gypsy Lore Soc.*, ser. 3, vol. 13, pts. 3–4) of Russian gypsy singers of to-day, the Ethnographical Department of the Russian Museum, Leningrad, has formed a gypsy choir selected from both town and nomad Gypsies, of which the repertoire includes all types of gypsy music from the traditional songs of the nomads—in the original form in which they had never been sung by the choirs of town Gypsies—to the Tsigane settings of modern music. Performances have been given in the State Theatre of the Ethnographical Department, of which the object is the preservation, study and presentation of the folk dances, songs and music of the various races under Soviet rule, such as, for example, the peoples of the Caucasus and the Ukraine and even, on occasion, of Turkestan. A similar gypsy studio is now attached to the State Theatre of Moscow.

Progress of Birth Control

THE second annual report, for 1931–32, of the National Birth Control Association has been issued by the Committee. The work of the Association has proceeded vigorously and has been stimulated by the general economic distress in Great Britain. Speakers on the subject of birth control have been supplied for meetings of various organisations. The Birth Control Investigation Committee is incorporated with the Association and investigations on spermaticides, contraceptive appliances, and statistics of birth control have been pursued. Local authorities to the number of 47 have decided to provide birth control advice within the terms of the Ministry of Health Circular No. 1208 of 1931. Terms of membership of the Association may be obtained from the Secretary, 26 Eccleston Street, London, S.W.1.

Greenkeeping Research

THE Golf Green Research Station at St. Ives, Bingley, continues its investigations into problems connected with the management of lawns. Vol. 2, No. 7 of its journal has recently appeared, and contains articles on "The Management of Golfing Turf on Heavy Soil" by G. Samuels, "Mole Draining of Golf Courses on Heavy Land" by R. B. Dawson, "Composts and Fertilisers in Relation to Greenkeeping" by T. W. Evans, "A Greenkeeper's Guide to the Grasses" by I. G. Lewis, and "Common Weeds of Turf" by R. B. Dawson. The Station has already made outstanding contributions to our knowledge of the ecology of the grasses which are used for lawns. Mr. R. B. Dawson and Dr. T. W. Evans have revolutionised our methods of manuring lawns, both of golf greens and garden and are substituting scientific knowledge for the 'rule of thumb' methods or the absence of methods, of the past. The journal may be obtained from the St. Ives Research Station, Bingley, Yorks., price 2*s*. 6*d*. per number.

Announcements

SIR ROBERT HADFIELD has been elected an honorary member of the Academy of Sciences of the U.S.S.R. in recognition of his work for metallurgy. The Soviet Ambassador in London, Mr. I. Maisky, is giving a luncheon in honour of the occasion on February 28.

MR. KENNETH HEADLAM-MORLEY has been appointed secretary of the Iron and Steel Institute in succession to Mr. G. C. Lloyd, who will retire shortly. Mr. Headlam-Morley was educated at Eton and Oxford, where he was a scholar at New College. He joined the staff of Messrs. Dorman Long and Co. Ltd. in 1925; after a technical training in their iron and steel works at Middlesbrough he has been occupied in their Secretarial, Managing Director's and By-Products Departments, and is well acquainted with the iron and steel industry of western Europe.

AT the annual general meeting of the Quekett Microscopical Club, held at 11, Chandos Street, Cavendish Square, W.1, on February 14, the following officers were elected: *President:* Mr. J. Milton Offord; *Vice-Presidents:* Mr. J. Wilson, Mr. C. D. Soar, Mr. J. Ramsbottom, Mr. E. A. Robins; *Treasurer:* Mr. C. H. Bestow; *Secretary:* Mr. W. S. Warton; *Reporter:* Mr. A. Morley-Jones; *Librarian:* Mr. C. H. Caffyn; *Curator:* Mr. C. J. Sidwell; *Editor:* Mr. W. S. Warton; *New Members of Committee:* Messrs. D. Bryce, W. J. Ireland, E. K. Maxwell, and E. C. Reeve.

A COURSE of six lectures on the design of photographic objectives will be given by Dr. W. D. Wright on Tuesdays and Thursdays commencing on February 28, at the Imperial College of Science and Technology, South Kensington, S.W.7. Further particulars can be obtained from the Registrar of the College.

MR. V. J. P. DE BLOCQ VAN KUFFELER, director of the Zuider Zee Works, will deliver an illustrated lecture, in aid of King Edward's Hospital Fund for London, on March 3, describing the way in which the reclamation of the Zuider Zee has been carried out under his supervision. The lecture will be at 5.30, at Drapers' Hall, Throgmorton Street, E.C.2. Admission will be by ticket obtainable either from the Secretary, King Edward's Hospital Fund for London, 7, Walbrook, E.C.4; or from Messrs. Alfred Hays, Ltd., 74, Cornhill, E.C.2; 26, Old Bond Street, W.1; and 62, Strand, W.C.2 but not at the doors.

WE have received from the Association of British Chemical Manufacturers and from the British Chemical Plant Manufacturers' Association, both of 166 Piccadilly, London, W.1, two publications entitled "British Chemicals 1933" and "Official Directory of Members 1933", respectively. These give the names and addresses of firms from whom various chemicals and types of plant are obtainable. The book on British chemicals is printed in several European languages. Copies may be obtained on application to the Association at the above address.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant at the Building Research Station, Garston—The Secretary, Department of Scientific and Industrial Research, 16, Old Queen Street, Westminster, S.W.1 (Feb. 28). A head of the School of Photography at the Polytechnic, Regent Street, London, W.1—The Director of Education (March 3). A teacher of engineering subjects and a teacher of mathematics at the Acton Technical College—H. M. Walton, Education Offices (H.), 10, Great George Street, London, S.W.1 (March 6). Two agricultural inspectors for the Department of Agriculture for Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (March 6). A research assistant in mental deficiency at the Royal Eastern Counties' Institution, Colchester—The Medical Superintendent, Royal Institution, Colchester (March 11). An assistant lecturer in geography at the University of Manchester—The Registrar (March 15). A Chaning Wills professor of geology at the University of Bristol—The Registrar (March 16). Three probationary assistant engineers in the Post Office Engineering Department—The Secretary, Civil Service Commission, Burlington Gardens, W.1 (March 16). A lecturer in geology at the University of Durham (Durham Division)—The Head of the Department of Science (March 20). A lecturer in medicine at the University of Aberdeen—The Secretary (March 21). A scientific assistant at the Imperial Bureau of Plant Genetics, School of Agriculture, Cambridge—The Director (March 30). Assistant examiners in the Patent Office—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1 (June 1).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Rubber Research

Many technologists other than those directly interested in rubber manufacture will have read with feelings of profound misgiving the leading article in Nature of February 11. The closing down of the Rubber Research Laboratory at Croydon and the dispersal of its fine library—one of the most complete special technical collections in Europe—would be nothing short of a catastrophe. For this is no moribund institution, but an active and extremely useful organisation discharging efficiently those duties and fulfilling those aims for which the industrial research associations were called into being.

Referring to the penultimate paragraph of the article, in which allusion is made to the benefits and obligations conferred upon industries by protection, it is only fair to state that the rubber manufacturing industry as a whole realises the benefits of co-operative research and accepts its obligations to maintain itself in a state of efficiency. It is therefore prepared to support the levy scheme as embodied in the Rubber Industry Bill, which it regards as the only workable scheme for securing the financial support necessary for the continuance of the Rubber Research Association. The fact that the Research Association numbers amongst its members no less than 86 rubber firms, including some of the largest in the country, affords ample evidence of the attitude of the majority of the industry in regard to the levy scheme and the Rubber Industry Bill. Yet, despite this preponderance of favourable opinion, the fact that the measure has perforce to be introduced into the House of Commons as a private member's Bill, apparently places it at the mercy of a minority opposition. Surely, in these circumstances, the efforts of the majority deserve the support not only of the Government, but also of all who have at heart the industrial progress of the future.

Regarding the volume and the character of the work which the Research Association has accomplished during the past thirteen years, I can speak with some knowledge. As chief chemist to a firm which has supported the Association throughout and as one well acquainted with its various activities, I can testify, as can many others in similar positions, to the very great practical value and usefulness of the many investigations which have been undertaken, and the results which have been obtained. Concerning the library side, it would be almost impossible to over-rate the value of the services rendered by the Association in the systematic collection, co-ordination and distribution of an enormous amount of scientific and technical information.

A study of the numerous research reports, in which the results of investigations have been published, affords ample evidence of the necessity for a separate organisation for the investigation of the common and fundamental problems of an industry. However well a firm makes provision for the scientific control of its own factory, it can seldom afford the time, staff or equipment required for the adequate study of these problems. From the point of view of economy also it is advisable that unnecessary repetition and overlapping should be avoided so far as possible and this can be ensured only by co-operation.

Attempts have been made in certain quarters to decry the value of the work of the Association but, so far as I am aware, no such attempts have been made by those who have studied, even superficially, the reports of the work done and results attained. Non-members, not having had this opportunity, can scarcely be considered competent to criticise on these grounds. To the minority who are opposing the Rubber Industry Bill, one would like to put the question: Have you any constructive suggestions as to what shall take the place of the organisation to which you object? It may be taken for granted that the objection is to co-operative research in principle.

What will be the effect if this opposition is successful in wrecking or unduly delaying the Bill? This Rubber Research Association, with its valuable plant and specially trained staff, its undeniable record of accomplishment, its library and its great potentialities for future service, will cease to exist. To the rubber industry this will be an irreparable loss, but it will have a far greater significance than that. It will be another blow, and possibly a knock-out blow, to the national movement for co-operative industrial research in connexion with which the Government itself has expended more than a million pounds.

Should the Bill pass to the statute book, however, the occasion may well mark the beginning of a new era for industrial research in which every industry will be able, without external assistance, to maintain and control a research organisation for investigating its own particular problems and for making contact, when necessary, with the similar organisations in other industries.

Hexuronic (Ascorbic) Acid as the Antiscorbutic Factor, and its Chemical Determination

Although it is known that specimens of hexuronic acid (since renamed ascorbic acid) possess antiscorbutic properties, it has remained to show whether this activity was an inherent property of the pure substance itself or ascribable to some associated impurity. Experiments to test the point have been carried out in this laboratory, as a result of which a very extensive and constant correlation has been established between vitamin C activity and hexuronic acid. Little doubt can therefore remain as to the identity of the two substances.

Our evidence may be summarised as follows:—(1) In preliminary work it was shown that the antiscorbutic activities of several natural sources ran approximately proportional to the amounts of hexuronic acid recoverable from them: thus suprarenal cortex (ox), not hitherto recognised as an antiscorbutic, had three times the potency of orange juice. (2) Specimens of hexuronic acid from different sources (suprarenal; paprika) were then assayed, and were found to have identical antiscorbutic activity. (3) Hexuronic acid after various repurification processes maintained its original activity. (4) The hexuronic acid contents of numerous natural sources were then determined chemically (by the method described below) and were found to account precisely for their known antiscorbutic activities. (5) In the case of several materials it was also possible to estimate the hexuronic acid content by intensity of absorption at 265 mμ (carried out by W. J. Dann), and this result was in further agreement with the biological or chemical tests. (6) The destruction of hexuronic acid by heat and aeration as measured chemically was found to proceed at a rate similar to that of vitamin C activity. (7) In the guinea pig the antiscorbutic activity of the suprarenal (or liver) was lost with the development of scurvy and this coincided with the disappearance of hexuronic acid. (8) With other species, the rat or dog, which are able to synthesise their own vitamin when none is provided in the diet, the antiscorbutic activity and the hexuronic acid both remain unaffected.

A rapid micro-chemical method has been devised for estimating the hexuronic acid content of foods, involving preliminary extraction with trichloracetic acid and titration against the oxidation-reduction indicator, 2, 6-dichlorophenolindophenol in acid solution. Certain naturally occurring reducing reagents, which were found to react when the reducing capacity of foodstuffs was determined according to the Tillmans technique in more neutral solution, did not interfere by this method (special precautions, however, being necessary in the presence of adrenaline). Sensitivity is about 1 part in 30; an amount of vitamin C represented by 0·03 c.c. of orange juice suffices for an accurate assay; and the determination requires only a few minutes to carry out. Results coincide with those obtained biologically. Values below are expressed as the 'minimal protective day dose' for guinea pig (figures in brackets being the determined or reputed values as measured biologically):

Cabbage 0·9 (1); watercress 1·3 (1); lemon juice 1·5, 1·5 (1·5); orange juice, several types 1·2, 1·5, 1·9 (1·5); grape fruit juice 1·4, 1·5 (1·5–2); pineapple juice 3 (2–3); imported tomato, juice of 4·3 (3–5); banana 6 (5–10); potato 6 (6–10); rhubarb 15 (12); carrots 32 (10–35); grapes 30 or above (> 20, 40); imported peach, juice of > 60 (–).

Horse-radish 0·6 (–).

Apples:—Bramley's seedling, cortex 5·5 (3–5), peel 1·2 (1); Newton, cortex 17 (10), peel 3·7 (3); Blenheim orange, cortex 29, peel 2·7; Edward VII, cortex 53 (> 20), peel 7·5 (2 ?); Cox's orange, cortex 56 (> 20), peel 10 (–).

Ox suprarenal cortex 0·5 (0·5); ox liver 1·3 (< 3); cows' milk 47 (20–60); "Ostermalt" 3·3 (–).

The exact antiscorbutic activity of hexuronic acid has been determined by several alternative methods (curative, tooth structure and preventive): 1·0 c.c. orange juice = 0·5 ± 0·15 mgm. hexuronic acid (or best values = 0·6 mgm.). We recommend its adoption as an international standard.
